RTD Analysis

Summary

## **No-Free-Lunch Theorem**

"There is no such thing as a free lunch."

- Refers to the nineteenth century practice in American bars of offering a "free lunch" with drinks.
- The meaning of the adage: *It is impossible to get something for nothing.*
- If something appears to be free, there is always a cost to the person or to society as a whole even though that *cost may be hidden or distributed*.

- NFL
- Decision problems
- Optim. problems
- Scenarios
- MC vs LV
- Theory vs practice

Empirical Comparisons

RTD Analysis

Summary

### **No-Free-Lunch Theorem**

"There is no such thing as a free lunch."

- Refers to the nineteenth century practice in American bars of offering a "free lunch" with drinks.
- The meaning of the adage: *It is impossible to get something for nothing.*
- If something appears to be free, there is always a cost to the person or to society as a whole even though that *cost may be hidden or distributed*.

### No-Free-Lunch theorem in search and optimization [WM97]

- Informally, for discrete spaces: "Any two (non-repeating) algorithms are equivalent when their performance is averaged across all possible problems."
- For a particular problem (or a particular class of problems), different search algorithms may obtain different results.
- If an algorithm achieves superior results on some problems, it must pay with inferiority on other problems.

- NFL
- Decision problems
- Optim. problems
- Scenarios
- MC vs LV
- Theory vs practice

### No-Free-Lunch theorem in search and optimization [WM97]

- Informally, for discrete spaces: "Any two (non-repeating) algorithms are equivalent when their performance is averaged across all possible problems."
- For a particular problem (or a particular class of problems), different search algorithms may obtain different results.
- If an algorithm achieves superior results on some problems, it must pay with inferiority on other problems.

It makes sense to study which algorithms are suitable for which kinds of problems!!!

Summary

### **Runtime Behaviour for Decision Problems**

### **Definitions:**

- lacksquare A is an algorithm for a class  $\Pi$  of decision problems.
- $RT_{A,\pi}$  is the runtime of algorithm A when applied to problem instance  $\pi$ ; random variable.
- $P_s(t) = P[RT_{A,\pi} \le t]$  is a probability that A finds a solution for a problem instance  $\pi \in \Pi$  in time less than or equal to t.

**Complete algorithm** *A* can provably solve any solvable decision problem instance  $\pi \in \Pi$  *after a finite time*, i.e. *A* is complete if and only if

$$\forall \pi \in \Pi, \ \exists t_{\max} : P_s\left(t_{\max}\right) = P[RT_{A,\pi} \le t_{\max}] = 1. \tag{1}$$

**Asymptotically complete algorithm** A can solve any solvable problem instance  $\pi \in \Pi$  with arbitrarily high probability *when allowed to run long enough*, i.e. A is asymptotically complete if and only if

$$\forall \pi \in \Pi : \lim_{t \to \infty} P_s(t) = \lim_{t \to \infty} P[RT_{A,\pi} \le t] = 1. \tag{2}$$

**Incomplete algorithm** *A* cannot be guaranteed to find the solution even if allowed to run infinitely long, i.e. if it is not asymptotically complete, i.e. *A* is incomplete if and only if

$$\exists \text{ solvable } \pi \in \Pi : \lim_{t \to \infty} P_s(t) = \lim_{t \to \infty} P[RT_{A,\pi} \le t] < 1. \tag{3}$$

Simple generalization based on transforming the optimization problem to a related decision problem by setting the solution quality target to  $q = r \cdot q^*(\pi)$ :

- $\blacksquare$  A is an algorithm for a class  $\Pi$  of optimization problems.
- $\blacksquare$   $RT_{A,\pi}$  is the runtime of algorithm A when applied to problem instance  $\pi$ ; random variable.
- $SQ_{A,\pi}$  is the quality of the solution found by algorithm A when applied to problem instance  $\pi$ ; random variable.
- $P_s(t,q) = P[RT_{A,\pi} \le t, SQ_{A,\pi} \le q]$  is the probability that A finds a solution of quality better than or equal to q for a solvable problem instance  $\pi \in \Pi$  in time less than or equal to t.
- $q^*(\pi)$  is the quality of optimal solution to problem  $\pi$ .
- $r \ge 1, q > 0.$

Simple generalization based on transforming the optimization problem to a related decision problem by setting the solution quality target to  $q = r \cdot q^*(\pi)$ :

- lacksquare A is an algorithm for a class  $\Pi$  of optimization problems.
- $\blacksquare$   $RT_{A,\pi}$  is the runtime of algorithm A when applied to problem instance  $\pi$ ; random variable.
- $SQ_{A,\pi}$  is the quality of the solution found by algorithm A when applied to problem instance  $\pi$ ; random variable.
- $P_s(t,q) = P[RT_{A,\pi} \le t, SQ_{A,\pi} \le q]$  is the probability that A finds a solution of quality better than or equal to q for a solvable problem instance  $\pi \in \Pi$  in time less than or equal to t.
- $q^*(\pi)$  is the quality of optimal solution to problem  $\pi$ .
- $r \ge 1, q > 0.$

**Algorithm** *A* **is** *r***-complete** if and only if

$$\forall \pi \in \Pi, \ \exists t_{\max} : P_s\left(t_{\max}, r \cdot q^*(\pi)\right) = P[RT_{A,\pi} \le t_{\max}, SQ_{A,\pi} \le r \cdot q^*(\pi)] = 1. \tag{4}$$

Simple generalization based on transforming the optimization problem to a related decision problem by setting the solution quality target to  $q = r \cdot q^*(\pi)$ :

- lacksquare A is an algorithm for a class  $\Pi$  of optimization problems.
- $\blacksquare$   $RT_{A,\pi}$  is the runtime of algorithm A when applied to problem instance  $\pi$ ; random variable.
- $SQ_{A,\pi}$  is the quality of the solution found by algorithm A when applied to problem instance  $\pi$ ; random variable.

Summary

## **Application Scenarios and Evaluation Criteria**

**Type 1:** Hard time limit  $t_{\text{max}}$  for finding solution; solutions found later are useless (real-time environments with strict deadlines, e.g., dynamic task scheduling or on-line robot control).

- $\Rightarrow$  Evaluation criterion:
  - dec. problems: solution probability at time  $t_{\text{max}}$ ,  $P_s$  ( $RT \le t_{\text{max}}$ )
  - opt. problems: expected quality of the solution found at time  $t_{\text{max}}$ ,  $E(SQ(t_{\text{max}}))$

■ Possible issue: What does "The expected solution quality of algorithm *A* is 2 times better than for algorithm *B*" actually mean?

## Monte Carlo vs. Las Vegas Algorithms

Classes of randomized algorithms:

- Monte Carlo algorithm (MCA): It always stops and provides a solution, but the solution may not be correct. The solution quality is a random variable. (Application scenario 1.)
- Las Vegas algorithm (LVA): It always produces a correct solution, but needs an unknown time to find it. The running time is a random variable. (Application scenario 2.)

How can we turn on type of algorithm into the other?

- LVA can often be turned into MCA by bounding the allowed running time.
- MCA can often be turned into LVA by restarting the algorithm from randomly chosen states (using a restarting scheme that systematically reduces unexplored holes in the search space).

Summary

## Theoretical vs. Empirical Analysis of LVAs

- Practically relevant LVAs are typically difficult to analyse theoretically.
- Cases in which theoretical results are available are often of limited practical relevance, because they
  - rely on idealised assumptions that do not apply to practical situations,
  - apply to worst-case or highly idealised average-case behaviour only, or
  - capture only asymptotic behaviour and do not reflect actual behaviour with sufficient accuracy.

Therefore, we often **analyse the behaviour of LVAs using empirical methodology**, ideally based on the *scientific method*:

- Make observations.
- Formulate hypothesis/hypotheses (model).
- While not satisfied with model (and deadline not exceeded):
  - 1. design computational experiment to test model
  - 2. conduct computational experiment
  - 3. analyse experimental results
  - 4. revise your model based on results

## **Empirical Algorithm Comparison**

## Empirical Comparisons

- Seconds vs counts

### Wall-clock time

- depends on the machine configuration, computer language, and on the operating system used to run the experiments (the results are neither comparable, nor reproducible);
- produces the (disastrous) incentive to invest a long time into implementation details, because they have a huge effect on this performance measure.

Since the objective function is often the most time-consuming operation in the optimization cycle, many authors use the **number of objective function evaluations** as the primary measure of "time".

## **Scenario 1: Limited time**

- For  $t_{\text{max,1}}$ , blue algorithm is better than red.
- For  $t_{\text{max,2}}$ , blue algorithm is worse than red.
- WARNING! The figure can change when  $t_{max}$  changes!!!

## Empirical Comparisons

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

#### RTD Analysis

Summary

### Student's t-test

### Independent two-sample t-test:

- Statistical method used to test if the means of 2 normally distributed populations are equal.
- The larger the difference between means, the higher the probability the means are different.
- The lower the variance inside the populations, the higher the probability the means are different.
- For details, see e.g. [Luk09, sec. 11.1.2].
- Implemented in most mathematical and statistical software, e.g. in MATLAB.
- Can be easily implemented in any language.

## Empirical Comparisons

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

### RTD Analysis

### Summary

## Student's t-test

### Independent two-sample t-test:

- Statistical method used to test if the means of 2 normally distributed populations are equal.
- The larger the difference between means, the higher the probability the means are different.
- The lower the variance inside the populations, the higher the probability the means are different.
- For details, see e.g. [Luk09, sec. 11.1.2].
- Implemented in most mathematical and statistical software, e.g. in MATLAB.
- Can be easily implemented in any language.

### Assumptions:

- Both populations should have normal distribution with equal variances.
- Almost never fulfilled with the populations of solution qualities.

Remedy: a non-parametric test!

[Luk09] Sean Luke. *Essentials of Metaheuristics*. 2009. available at http://cs.gmu.edu/~sean/book/metaheuristics/.

## Empirical Comparisons

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

#### RTD Analysis

### Summary

## **Mann-Whitney U test**

Non-parametric test assessing whether two independent samples of observations have equally large values.

- Virtually identical to:
  - combine both samples (for each observation, remember its original group),
  - sort the values,
  - replace the values by ranks,
  - use the ranks with ordinary parametric two-sample t-test.
- The measurements must be at least ordinal:
  - We must be able to sort them.
  - This allows us to merge results from runs which reached the target level with the results of runs which did not.

### Scenario 2: Prescribed target level

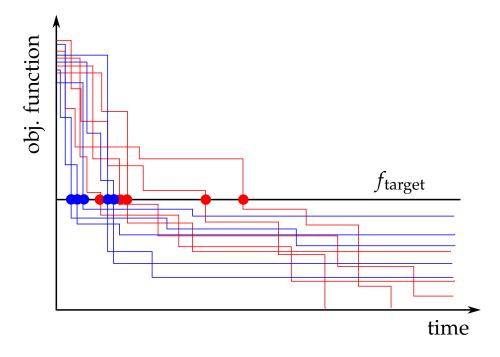

Let them run until they find a solution of certain quality  $f_{\text{target}}$  and compare the average runtime, ave(RT)

#### Motivation

# Empirical Comparisons

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

#### RTD Analysis

### Scenario 2: Prescribed target level

Let them run until they find a solution of certain quality  $f_{\text{target}}$  and compare the average runtime, ave(RT)

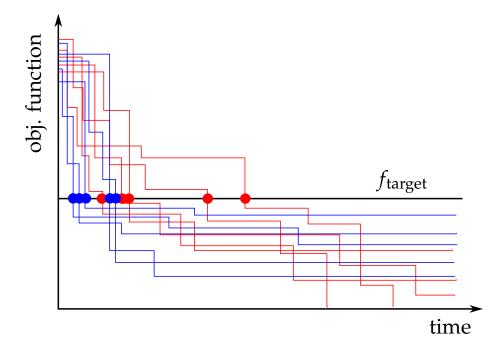

#### Motivation

# Empirical Comparisons

- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

RTD Analysis

Summary

■ For  $f_{\text{target,1}}$ , blue algorithm is better than red.

### Scenario 2: Prescribed target level

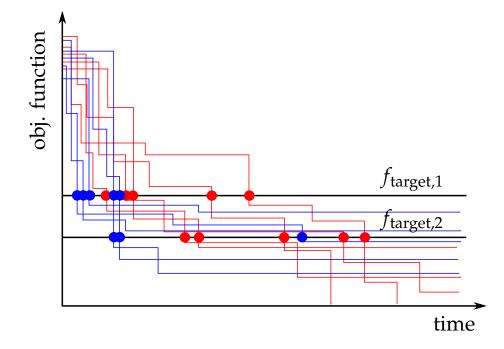

Let them run until they find a solution of certain quality  $f_{\text{target}}$  and compare the average runtime, ave(RT)

#### Motivation

#### **Empirical** Comparisons

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

#### RTD Analysis

- For  $f_{\text{target},1}$ , blue algorithm is better than red.
- For  $f_{\text{target,2}}$ , blue algorithm still seems to better than red (if it finds the solution, it finds it faster), but 2 blue runs did not reach the target level yet, i.e. (we are much less sure that blue is better).
- WARNING! The figure can change when  $f_{\text{target}}$  changes!!!

## Empirical Comparisons

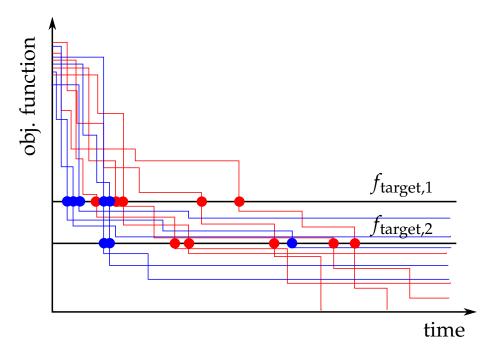

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

#### RTD Analysis

Summary

### Scenario 2: Prescribed target level

Let them run until they find a solution of certain quality  $f_{\text{target}}$  and compare the average runtime, ave(RT)

- For  $f_{\text{target},1}$ , blue algorithm is better than red.
- For  $f_{\text{target,2}}$ , blue algorithm still seems to better than red (if it finds the solution, it finds it faster), but 2 blue runs did not reach the target level yet, i.e. (we are much less sure that blue is better).
- WARNING! The figure can change when  $f_{\text{target}}$  changes!!!
- The same statistical tests as for scenario 1 can be used.

### Scenarios 1 and 2 combined

Let them run until they find a solution of certain quality  $f_{\text{target}}$  or until they use all the allowed time  $t_{\text{max}}$ .

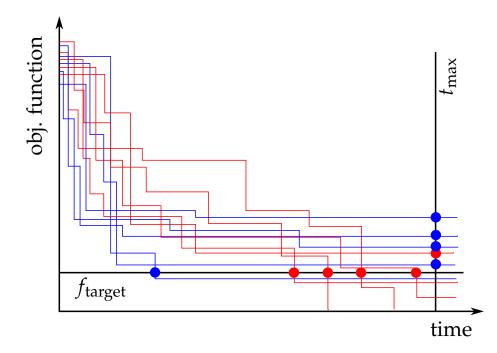

# Empirical Comparisons • Seconds vs counts • Scenario 1

- Scenario 2
- S1 and S2 combined

RTD Analysis

Summary

■ *RT* is measured in seconds or function evaluations, *SQ* is measured in something different; now, how can we test if one algorithm is better than the other?

### Scenarios 1 and 2 combined

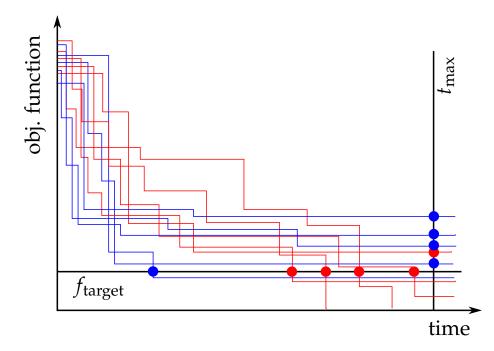

Let them run until they find a solution of certain quality  $f_{\text{target}}$  or until they use all the allowed time  $t_{\text{max}}$ .

### Empirical Comparisons

Motivation

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

RTD Analysis

- *RT* is measured in seconds or function evaluations, *SQ* is measured in something different; now, how can we test if one algorithm is better than the other?
- The situation when the algorithm reaches  $f_{\text{target}}$  is better than when it reaches  $t_{\text{max}}$ . We can still sort the values.
- We can use the Mann-Whitney U-test.

# Empirical Comparisons

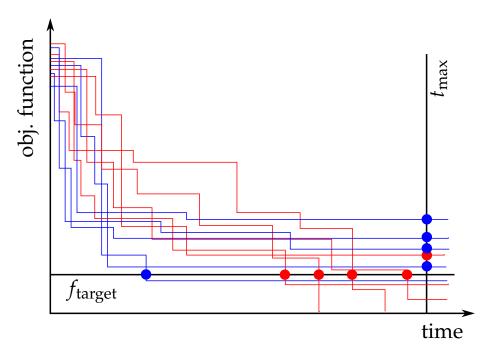

- Seconds vs counts
- Scenario 1
- Student's t-test
- MWUT
- Scenario 2
- S1 and S2 combined

#### RTD Analysis

Summary

### Scenarios 1 and 2 combined

Let them run until they find a solution of certain quality  $f_{\text{target}}$  or until they use all the allowed time  $t_{\text{max}}$ .

- *RT* is measured in seconds or function evaluations, *SQ* is measured in something different; now, how can we test if one algorithm is better than the other?
- The situation when the algorithm reaches  $f_{\text{target}}$  is better than when it reaches  $t_{\text{max}}$ . We can still sort the values.
- We can use the Mann-Whitney U-test.
- WARNING! Again, if we change  $f_{\text{target}}$  and/or  $t_{\text{max}}$ , the figure can change!!!

Summary

### **Runtime distributions**

LVAs are often designed and evaluated without apriori knowledge of the application scenario:

- Assume the most general scenario type 3 with a utility function (which is often, however, unknown as well).
- Evaluate based on solution probabilities  $P_s(t,q) = P[RT \le t, SQ \le q]$  for arbitrary runtimes t and solution qualities q.

Study distributions of *random variables* characterising runtime and solution quality of an algorithm for the given problem instance.

Summary

### **RTD** defintion

Given a Las Vegas alg. *A* for optimization problem  $\pi$ :

The *success probability*  $P_s(t,q) = P[RT_{A,\pi} \le t, SQ_{A,\pi} \le q]$  is the probability that A finds a solution for a solvable instance  $\pi \in \Pi$  of quality  $\le q$  in time  $\le t$ .

- RTD
- RTD defintion
- RTD cross-sections
- Measuring RTD
- RTD comparisons
- Example

Summary

Horizontal cross-sections reveal the dependence of *SQ* on *RT*:

■ The lines represent various quantiles; e.g. for 75%-quantile we can expect that 75% of runs will return a better combination of *SQ* and *RT*.

- Example

Summary

### **Empirical measurement of RTDs**

Empirical estimation of  $P[RT \le t, SQ \le q]$ :

- Perform N independent runs of A on problem  $\pi$ .
- For  $n^{\text{th}}$  run,  $n \in 1, ..., N$ , store the so-called *solution quality trace*, i.e.  $t_{n,i}$  and  $q_{n,i}$  each time the quality is improved.
- $\hat{P}_s(t,q) = \frac{n_S(t,q)}{N}$ , where  $n_S(t,q)$  is the number of runs which provided at least one solution with  $t_i \le t$  and  $q_i \le q$ .

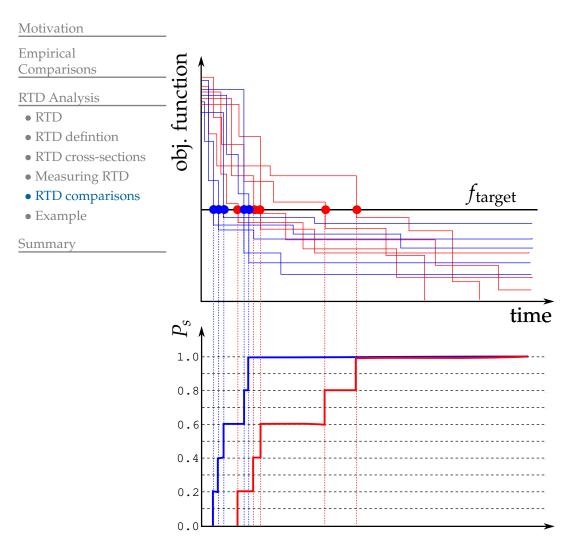

Empirical RTDs are approximations of an algorithm's true RTD:

 $\blacksquare$  The larger the N, the better the approximation.

### RTD based algorithm comparisons

E.g. type 2 application scenario: set  $f_{\text{target}}$  and compare RTDs of the algorithms

### RTD based algorithm comparisons

E.g. type 2 application scenario: set  $f_{\text{target}}$  and compare RTDs of the algorithms

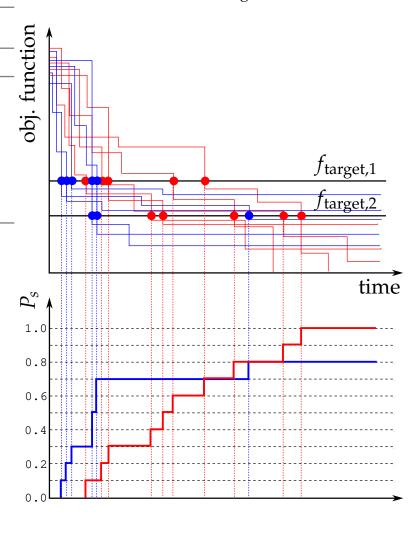

...and add another  $f_{\text{target}}$  level ...

- RTD comparisons
- Example

Summary

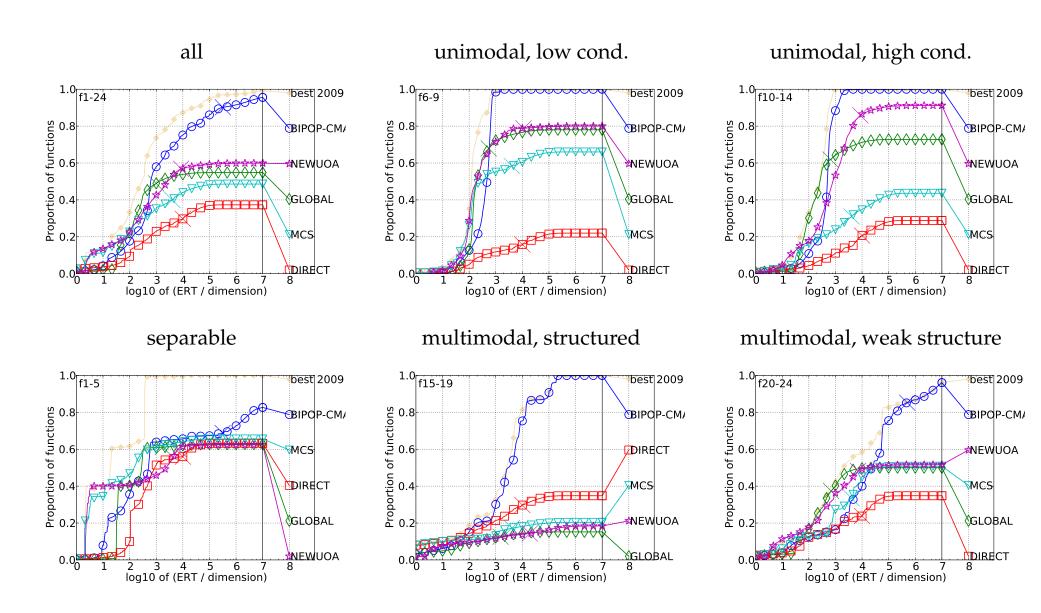

This way we can aggregate RTDs of an algorithm *A* not only

- over various  $f_{\text{target}}$  levels, but also
- over different problems  $\pi \in \Pi$  (!!!), of course with certain loss of information.

### **Example of comparison**

RTD Analysis

Summary

• Learning outcomes

### **Learning outcomes**

After this lecture, a student shall be able to

- explain No Free Lunch Theorem, and its consequences;
- explain the concepts of success probability, runtime distribution, solution quality, and their relationship;
- $\blacksquare$  define *r*-complete, asymptotically *r*-complete, and *r*-incomplete algorithms;
- describe 3 usual scenarios of applying an algorithm to an optimization problem, and explain their differences;
- explain differences between Monte Carlo and Las Vegas algorithms;
- name the advantages and disadvantages of measuring time in seconds vs measuring time in the number of performed operations;
- explain what errorneous conclusions can be drawn from the results of an experiment when comparing algorithms using a single time limit, and/or a single required target level;
- know a few statistical test that can be used to compare 2 algorithms;
- exemplify what kind of characteristics we can get when taking cross-sections of the runtime distribution function;
- explain how the runtime distributions can be aggregated over different target levels, different problem instances and different problems;
- derive valid conclusions when presented with runtime distributions of two or more algorithms.
