# State Space Search

- So far we have considered planning as search in **state space**
  - **forward** - build a plan in the same order that it is executed
  - **backward** - build a plan in the reverse order of its execution
  - **temporal undirected** - unordered commitments on executing actions in time

# State Space Search

- **Potential problem:** Spending lots of time on trying the same set of actions in different orderings before realizing that there is no solution (with this set)
  - Easier to see in FS/BS, and a bit harder to see in TUS.
- **Key observation:** When we choose **what** to do, we also choose **when** to do

# Searching in the Space of Plans

- In 1974, Earl Sacerdoti built a planner, called *NOAH*, that considered planning as search through **plan space**
  - Search states (nodes) = **partially specified plans**
  - Transitions (edges) = **plan refinement operations**
  - Initial state = **null plan**
  - Goal states = **valid plans** for the problems

Automated

# State Space vs. Plan Space

- Search through plan space ... hmm ... *what is plan?*
- Answer I: Totally ordered sequence of either actions or meta-actions
  - But then search through state space is **isomorphic** to search through plan space!
  - Hmm ... the nature of the space being searched is in the eye of the beholder ...
  - So what is the point of introducing “search through plan space”??
- Answer II: **Partially ordered** sequence of actions

# Partial-Order Plans

- Given a Strips task  $\Pi = (P, A, I, G)$  we search through a space of *hypothetical partial-order plans*
- A plan (= search node) is a triplet:  $\langle \mathcal{A}, \mathcal{O}, \mathcal{L} \rangle$  in which
  - $\mathcal{A}$  is a set of **actions** from  $A$ , possibly with (labeled) repetitions
  - $\mathcal{O}$  is a set of **ordering constraints** over  $\mathcal{A}$
  - $\mathcal{L}$  is a set of **causal links** (a bit later)
- Example:  $\mathcal{A} = \{a_1, a_2, a_3\}$ ,  $\mathcal{O} = \{a_1 < a_3, a_2 < a_3\}$
- Observe: Planner (eventually) must do constraint satisfaction to ensure the **consistency** of  $\mathcal{O}$ .

# Causal Links

A key aspect of least commitment planning is to keep track of past decisions and the *reasons* for those decisions

- If you purchase plane tickets, then make sure bring them to the airport
- If another goal causes you to drop the tickets (e.g., having your hands free to open the taxi door), then you should be sure to pick them up again.
- A good way to reason about (and act for) non-interference between different actions introduced to the plan is to record dependencies between actions *explicitly*
- **Causal links**  $a_p \xrightarrow{q} a_c$  records our decision to use  $a_p$  to produce the precondition  $q$  of  $a_c$

# Threats

- Causal links are used to detect when a newly introduced action interferes with past decisions.
- Such an action is called a **threat**
- Suppose that
  - $a_p \xrightarrow{q} a_c$  is a causal link in  $\mathcal{L}$  (of some plan  $\langle \mathcal{A}, \mathcal{O}, \mathcal{L} \rangle$ ), and
  - $a_t$  is yet another action in  $\mathcal{A}$
- We say that  $a_t$  **threatens**  $a_p \xrightarrow{q} a_c$  if
  - $\mathcal{O} \cup \{a_p < a_t < a_c\}$  is consistent, and
  - $q \in \text{del}(a_t)$

# Eliminating Threats

- When a plan contains a threat, then it is *possible* that the plan would not work as anticipated.
  - *Which means what?*
- Solution: identify threats and take evasive countermeasures
  - **promotion** by  $\mathcal{O} \cup = \{a_t > a_c\}$
  - **demotion** by  $\mathcal{O} \cup = \{a_t < a_p\}$
  - ...

# Planning Problems as Null Plans

Uniformity is the key for simplicity

- Can use the same structure to represent both the planning problem and complete plans
- Planning problem as a **null plan**  $\langle \mathcal{A}, \mathcal{O}, \mathcal{L} \rangle$  where
  - $\mathcal{A} = \{a_0, a_\infty\}$ ,  $\mathcal{O} = \{a_0 < a_\infty\}$ ,  $\mathcal{L} = \{\}$
  - $\text{pre}(a_0) = \{\}$ ,  $\text{del}(a_0) = \{\}$ ,  $\text{add}(a_0) = I$
  - $\text{pre}(a_\infty) = G$ ,  $\text{del}(a_\infty) = \{\}$ ,  $\text{add}(a_\infty) = \{\}$

# The POP Algorithm

## Schematic description

Regressive algorithm that searches plan-space

- Starts with the null plan
- Makes *non-deterministic* plan refinement choices until
  - all preconditions of all actions in the plan have been supported by causal links, and
  - all threatened causal links have been protected from possible interference

# The POP Algorithm

## Input and Output

Recursive calls to *POP* with  $POP(\langle \mathcal{A}, \mathcal{O}, \mathcal{L} \rangle, agenda, A)$

where

- $\langle \mathcal{A}, \mathcal{O}, \mathcal{L} \rangle$  is a plan structure
- *agenda* is a list of “open goals” that need to be supported by causal links
- *A* is the action set of our Strips problem

Initial call is with

- null plan  $\langle \{a_0, a_\infty\}, \{a_0 < a_\infty\}, \{\} \rangle$ , and
- $agenda = \{(g, a_\infty) \mid g \in \text{pre}(a_\infty) \equiv G\}$

If  $\langle \mathcal{A}, \mathcal{O}, \mathcal{L} \rangle$  is outputted by *POP*, then *any* total ordering of actions  $\mathcal{A}$  consistent with  $\mathcal{O}$  is a valid plan for our problem.

## Example - Step 2

Suppose that an **oracle** suggests making  $a_{add}$  be a new instance of the action *move-B-from-Table-to-C*

- a causal link  $a_{add} \xrightarrow{\text{onBC}} a_{\infty}$  is added to  $\mathcal{L}$
- *agenda* is properly updated (*how exactly?*)
- no threats to resolve ... recursive call

**\*start\***  
(on c a) (clear b) (clear c) (on a table) (on b table)

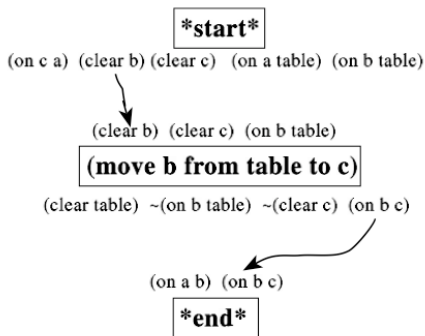

(clear b) (clear c) (on b table)  
**(move b from table to c)**  
(clear table) ~(on b table) ~(clear c) (on b c)

(on a b) (on b c)

**\*end\***

## Example - Step 3

- Suppose *(clearB, move-B-from-Table-to-C)* is selected
- Oracle suggests to reuse an **existing** action instance  $a_0$ 
  - add a causal link  $a_0 \xrightarrow{\text{clearB}} \text{move-B-from-Table-to-C}$
  - *agenda* is properly updated (*how exactly?*)
  - no threats to resolve ... recursive call

# Example - Step 4a

- Suppose  $(\text{onAB}, a_\infty)$  is selected
- Oracle suggests making  $a_{add}$  be a new instance of the action *move-A-from-Table-to-B*, and we do that ...
- ... BUT this time we have a **threat!**
  - *move-A-from-Table-to-B* and *move-B-from-Table-to-C* have no constraints on their relative ordering
  - *move-A-from-Table-to-B* deletes `clearB` that is required by *move-B-from-Table-to-C*

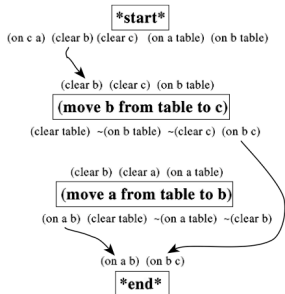

# Example - Step 4b

Try to **protect** the causal link

$a_0 \xrightarrow{\text{clearB}} \text{move-B-from-Table-to-C}$

- In general, there are two options — *promotion* and *demotion* — and this is a true non-deterministic choice!
- In our example, demotion is inconsistent (*why?*), but promotion is OK

# Example - Next steps

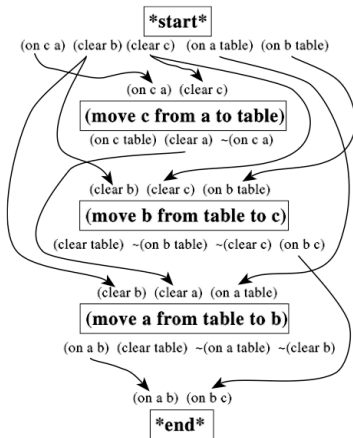

- What is now on the *agenda*? ... in  $\mathcal{A}$ ? ... in  $\mathcal{L}$ ? ... in  $\mathcal{O}$ ?

- Next steps follow the same lines of reasoning

# Example - Next steps

- Eventually *POP* returns

- Blackboard: *Is it a correct partial order plan?*

# Advantages

- Natural extension to planning with **partially instantiated actions**
  - ... add action instance *move-A-from-x?-to-B*
  - ... postpone unifying  $?x$  with a concrete object until necessary
- Natural extensions to more complex **action formalisms**
  - ... action durations
  - ... delayed effects
  - ...
- Least commitment may lead to shorter search times
  - Mainly due to smaller **branching factor**

- **Solution plan:** set  $\rho$  of couples  $\langle a_i, t_i \rangle, i = 1, \dots, n$  st:
  - $a_i \in A$  and  $t_i$  starting time of the application of  $a$
  - $\forall \langle a_i, t_i \rangle \in \rho, pre(a_i)$  true at time  $t_i$
  - $\forall g \in G, g$  true at time  $\max_{\langle a_i, t_i \rangle \in \rho} [t_i + dur(a_i)]$
  - $\forall \langle a_i, t_i \rangle, \langle a_j, t_j \rangle \in \rho$ , if  $a_i$  and  $a_j$  interfere, then they do not overlap.

## Goal

Develop an **optimal temporal planner** with **good performance**

# Optimal planning is branching and pruning

**Branching** is used for expanding partial solutions

**Pruning** is used for discarding them

Optimal **state-based** planners:

- **Branch** by performing state progression or regression
- **Prune** by comparing the estimated cost of the partial plan with a given bound

Optimal **SAT** and **CSP** planners:

- **Branch** by picking a variable and trying each of its values
- **Prune** by backtracking over inconsistencies due to encoded bounds

# Pruning: A key feature of modern planners

- In heuristic search planners achieved by use of **lower bounds** or **admissible heuristics**
- In SAT and CSP approaches achieved by adding the goal at a fixed bound and performing **constraint propagation**
- Both ideas combined in SAT/CSP formulations obtained from **planning graph** (that contains lower bounds)

# POCL: Smart but blind branching scheme

## POCL branching main loop:

- Find and repair a "flaw" till not possible (and then backtrack) or done
- Flaws: open conditions, threats, ...

**Benefit:** easy to extend to temporal planning

**Problem:** weak pruning mechanism; detects very late that partial plan is not good

Automated

# Benefit POCL branching: Easy to add time

- Partial ordering  $a < a'$  over actions replaced by **temporal precedence** constraint  $T(a) + dur(a) \leq T(a')$
- Consistency over resulting **Simple Temporal Problem** easy to enforce by **bounds consistency**:

*Iterate over*

$$T_{max}(a) := \min[T_{max}(a), T_{max}(a') - dur(a)]$$

$$T_{min}(a') := \max[T_{min}(a'), T_{min}(a) + dur(a)]$$

*until fixed-point or some empty variable domain*

- Expressive planners based on this formulation are IxTeT, RAX...

# Problem POCL planning: Weak pruning

Backtrack when partial plan or STP inconsistent.

↪ Need to detect “bad partial plans” earlier

## Example: TOWER-N problems

- Initial state:  $N$  blocks  $b_i$  lie on the table
- Goal:  $\forall i \in [1, \dots, N - 1], on(b_i, b_{i+1})$

One partial plan:

$$\langle stack(b_{i+1}, b_{i+2}), t \rangle, \langle stack(b_i, b_{i+1}), t + 2 \rangle$$

Open condition for  $\langle stack(b_i, b_{i+1}), t + 2 \rangle$ :

$$\langle holding(b_i), t + 2 \rangle$$

# Problem POCL planning: Weak pruning

Possible repairs:

- $\langle \text{pickup}(b_i), t + 1 \rangle$   
 $\implies$  **1 good choice:** can lead to a solution
- $\langle \text{pick}(b_i, b_j), t + 1 \rangle$ , for all  $j \in [1..N], i \neq j$   
 $\implies$  **N-1 bad choices:** backtrack (later) because do not lead to optimal solutions

Recent attempts (RePop, VHPOP) for guiding search but no optimality guarantees

Proposed approach

Solves TOWER-N problems **optimally** and **backtrack free**

# Additional scheduling technique: Mutex sets

Based on scheduling technique **edge-finding**:

- A mutex set is a set  $M$  of actions *in the plan*, such that any two actions in  $M$  are interfering.
- The time window associated with the set of actions  $M$ ,  $\max_{a \in M} (T_{max}(a) + dur(a)) - \min_{a \in M} T_{min}(a)$ , must provide enough 'room' for scheduling all actions in  $a \in M$  in sequence.
- Lower bound  $\Delta(M)$  for the time needed for scheduling all actions in  $M$  is given by

$$\sum_{a \in M} [dur(a) + \min_{a' \in M | a' \neq a} dist(a, a')] - \max_{\{a, a'\} \subseteq M} dist(a, a')$$

# Non-canonical planning with CPT

Automated  
(AI) Planning

The current version of CPT finds **non-canonical plans**.

## Key ideas:

- Distinguish action **types** from action **tokens**
- Tokens are **generated dynamically** from action types

## Implementation:

- Emulates domain that contains an **infinite supply of tokens**
- Variables associated with such tokens are **identical** until a token becomes part of the plan

# Summary

- **Optimal temporal planner** with performance that approaches best parallel planners over domains with uniform durations
- Combines **POCL temporal branching scheme** with **strong pruning mechanisms** based on the use of a variety of constraints and existing lower bounds

# Optimal, Suboptimal and Easy planning

Automated  
(AI) Planning

- **Optimal planning:** minimizes plan makespan.

Examples: GRAPHPLAN, IPP, SATPLAN, GP-CSP, TP4, CPT...

From  
state-space to  
plan-space  
search

- **Suboptimal planning:** no guarantee on plan quality, tries to minimize the number of actions in the plan.

Examples: HSP, FF, LPG, SAPA...

Least  
Commitment  
Planning

- **Easy planning:** same as suboptimal planning, with the objective of **privilege inferences over search**.

Example: eCPT.

Meeting

Privileging  
Inference

Temporal planner for easy planning that solves as much problems as possible **without search**.

From  
state-space to  
plan-space  
search

Least  
Commitment  
Planning

Meeting  
POCL and  
Planning-as-  
CSP

Privileging  
Inference

Without search means:

- Avoid backtracks,
- Privilegiate inferences over search,
- Add only polynomial operations,
- Analyse the results from the point of view of general behavior (backtracks, ...) instead of running time.

# Difficulty of easy planning

- Very few planners perform inferences, some examples are SATPLAN, GP-CSP and CPT.
- To render them “easy”: increase the lower bound on the makespan (the horizon).

## Two problems appear:

- 1 The size of the encodings based on one variable per time unit **increases too much**,
- 2 Constraints that require the validity of the goals at the horizon **lose their pruning power**.

# Impossible supports

Automated  
(AI) Planning

Supports elimination by preprocessing.

Example:

- $unstack(A, B)$  has  $handempty$  as precondition
- $putdown(A)$  adds  $handempty$  so

$$putdown(A) \in D[S(handempty, unstack(A, B))]$$

$\implies$  but:  $putdown(A)$  e-deletes  $on(A, B)$ , precondition of  $unstack(A, B)$

$\implies$  furthermore:  $on(A, B)$  cannot be re-established without deleting  $handempty$

For each variable  $S(p, a)$  and each value  $a' \in D[S(p, a)]$ :

- let  $I' = P \setminus edel(a')$
- let  $A' = A \setminus \{a \in A \mid p \in add(a) \cup del(a)\}$
- reachability analysis with  $I'$  and  $A'$

$\implies$  if a precondition of  $a$  is not reachable:  $S(p, a) \neq a'$

# Unique supports

Automated  
(AI) Planning

Pruning rule used during constraint propagation.

Example:

- $unstack(A, B)$  and  $pickup(C)$  have  $handempty$  as precondition and delete,
- they cannot be applied in parallel,
- after the application of one of them,  $handempty$  is deleted.

⇒ the action that supports  $handempty$  for the first cannot support  $handempty$  for the second.

# Unique supports

- An action  $a$  **consumes** an atom  $p$  when

$$p \in pre(a) \cap del(a)$$

- For two actions  $a$  and  $a'$  that consumes the same atom  $p$ , **the following constraint is added:**

$$S(p, a) \neq S(p, a')$$

# Distance boosting

Increases distances and prunes supports by preprocessing.

Example:

- The distance between  $putdown(A)$  and  $pickup(A)$  is equal to 0.  
⇒ However, applying  $putdown(A)$  then  $pickup(A)$  is useful only if an action inserted between them uses an effect of  $putdown(A)$ , for example if  $A$  is on a block  $B$  that we want to move.
- Similarly, the distance between  $pickup(A)$  and  $putdown(A)$  is equal to 0.  
⇒ But: no action can be inserted between them that uses an effect of  $pickup(A)$ .

# Distance boosting

Automated  
(AI) Planning

An action  $a$   **cancels**  an action  $a'$  when

- All atoms added by  $a'$  are e-deleted by  $a$ ,
- All atoms added by  $a$  are preconditions of  $a'$ .

For an action  $a$  that cancels an action  $a' \in D[S(p, a)]$ :

- If all actions that use an add effect of  $a'$  e-delete  $p$ :  
 $S(p, a) \neq a'$ .
- Else:  $dist(a', a)$  becomes  $\min_b [dist(a', b) + dist(b, a)]$   
with  $b \neq a$  and  $b \neq a'$ , such that
  - either  $b$  uses an add effect of  $a'$  but does not e-delete  $p$ ,
  - or  $b$  adds  $p$ .

# Qualitative precedences

CPT reasons with **temporal precedences** of the form  $T(a) + \delta(a, a') \leq T(a')$  instead of **qualitative precedences**.

⇒ Problem: they does not capture **transitivity**.

For exemple: from  $a < b$  and  $b < c$ , CPT does not infer  $a < c$ .

- the initial domain of variables  $a$ ,  $b$ , and  $c$  is  $[1, \dots, 100]$ ,
- by bounds consistency:

$$a :: [1, \dots, 98], b :: [2, \dots, 99], c :: [3, \dots, 100]$$

⇒ does not make  $a < c$  true for every combination of values

# Qualitative precedences

When a temporal precedence is made true: a qualitative precedence is recorded. For  $a \prec a'$ , the transitive closure is computed:

- if  $InPlan(a) = 1$ :  $\forall a''$  st  $a'' \prec a$ ,  $a'' \prec a'$  is inferred
- if  $InPlan(a') = 1$ :  $\forall a''$  st  $a' \prec a''$ ,  $a \prec a''$  is inferred

Inference rules using these qualitative precedences:

- for an action  $a' \in D[S(p, a)]$ :
  - if  $InPlan(a') = 1$  and  $a \prec a'$  then  $S(p, a) \neq a'$
- for an action  $a' \in D[S(p, a)]$  and an action  $b$  that e-deletes  $p$ :
  - if  $InPlan(b) = 1$ ,  $a' \prec b$  and  $b \prec a$ , then  $S(p, a) \neq a'$

# Landmark actions

By preprocessing: we can find **some actions that must belong to any solution plan**.

For example:

- a block  $A$  must be moved,
- $A$  is under  $B$ , itself under  $C$ .

$\implies$   $unstack(C, B)$  and  $unstack(B, A)$  must be used **in any solution plan**, and  $unstack(C, B) \prec unstack(B, A)$ .

- An action  $a$  is a landmark if a goal of the problem is not reachable when  $a$  is excluded from the domain.
- An action landmark  $a$  precedes an action landmark  $b$ , if  $b$  is not reachable when the action  $a$  is excluded.

# Branching and heuristics

**Support threats**  $\langle a', S(p, a) \rangle$ :

- 1 to minimize  $T_{min}(a)$
- 2 to minimize  $T_{max}(p, a)$
- 3 to minimize  $\max[\text{slack}(a' \prec S(p, a)), \text{slack}(a \prec a')]$

where:

$$\text{slack}(a, a') = T_{max}(a') - [T_{min}(a) + \delta(a, a')]$$

$$\text{slack}(a', S(p, a)) =$$

$$T_{max}(p, a) - [T_{min}(a') + \min_{a' \in D[S(p, a)]} \delta(a', a)]$$

**Open conditions**  $S(p, a)$ :

- 1 to minimize  $T_{max}(p, a)$
- 2 to minimize  $\text{slack}(a', a) = T_{max}(a) - (T_{min}(a') + \delta(a', a))$   
where  $a'$  produces  $p$  for  $a$  ( $a' \in D[S(p, a)]$ ), minimizing  $T_{min}(a')$ .

# Discussion

- **Unexpected results:** a few simple inference rules are sufficient to avoid backtracks in many benchmarks.
- **Interest of the CP+POCL formulation:** it has permitted the fine-grained analysis of backtracks and finding new rules.
- **Inferences have a cost:** actually, methods that privilege search are more efficient.
- **Robustness improvement:** in the domains studied, we almost sure get a solution in reasonable time.
