Morphology

- Morphology deals with form and structure
- Mathematical morphology is a tool for extracting image components useful in:
 - representation and description of region shape (e.g. boundaries)
 - pre- or post-processing (filtering, thinning, etc.)
- Based on set theory

Definitions: Let A and B be binary images, p and q two pixels with indices $[i, j]$ y $[k, l]$ respectively, and Ω the universal binary image.

Union:

$$A \cup B = \{p | p \in A \vee p \in B\}$$

Intersection:

$$A \cap B = \{p | p \in A \wedge p \in B\}$$

Complement:

$$\bar{A} = \{p | p \in \Omega \wedge p \notin A\}$$

Difference:

$$A - B = A \cap \bar{B}$$

Translation:

$$A_p = \{a + p | a \in A\}$$

- Vectorial sum:

$$p + q = [i + k, j + l]$$

- Vectorial difference:

$$p - q = [i - k, j - l]$$

Reflex:

$$A' = \{-p | p \in A\}$$

(b) Reflection of B . The sets A and B are from Fig. 9.1.

Dilation & Erosion

- The value of the output pixel is the *maximum* value of all the pixels in the input pixel's neighborhood.

- Dilation:
$$A \oplus B = \{x \mid [(\hat{B})_x \cap A] \subseteq A\}$$

- B is the **structuring element** in dilation.

- The value of the output pixel is the *minimum* value of all the pixels in the input pixel's neighborhood.

- Erosion:

$$A \ominus B = \{x \mid (B)_x \subseteq A\}$$

Dilation & Erosion

A

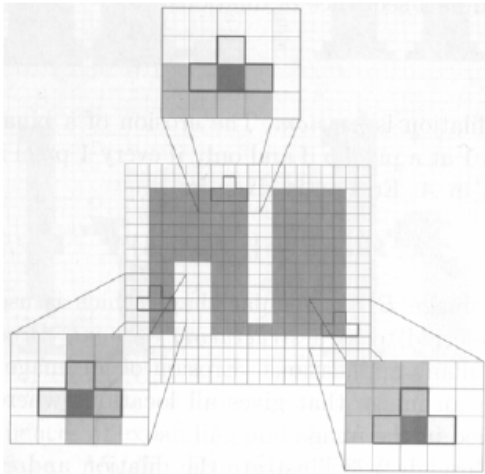

B

- **Dilation:** union of translations of an image **A** by each pixel of image **B**, called *structural element*:

$$A \oplus B = \bigcup_{b_i \in B} A_{b_i}$$

- **Erosion** inverse operation

$$A \ominus B = \{p | B_p \subseteq A\}$$

Opening & Closing

- In essence, dilation expands an image and erosion shrinks it.
 - **Opening:**
 - generally smoothes the contour of an image, breaks isthmuses, eliminates protrusions.
 - **Closing:**
 - smoothes sections of contours, but it generally fuses breaks, holes, gaps, etc.
- **Opening** of A by structuring element B:

$$A \circ B = (A \ominus B) \oplus B$$

- **Closing:**

$$A \bullet B = (A \oplus B) \ominus B$$

- **Opening:** erosion + dilation with the same element

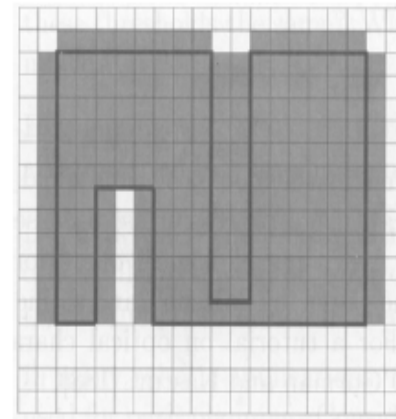

$$A \circ K = (A \ominus K) \oplus K$$

- Eliminates all regions too small to contain the structural element

- **Closing:** dilation + erosion with the same element

$$A \bullet K = (A \oplus K) \ominus K$$

- Fills all holes and cavities smaller than the structural element

- **Skeletons, axis of symmetry S^* :**
geometric place of the centers of all at least bi-tangent circles.

- S^* is a compact representation of S ; it represents the *shape* of the region.

- Highly sensitive to noise.

The frontier is also a compact representation of shape.

Thinning

$$A \odot B^l = A - (A \otimes B^l)$$

$$X_0 = A$$

$$X_k = X_{k-1} \odot B^{\{1, \dots, n\}}$$

Final result

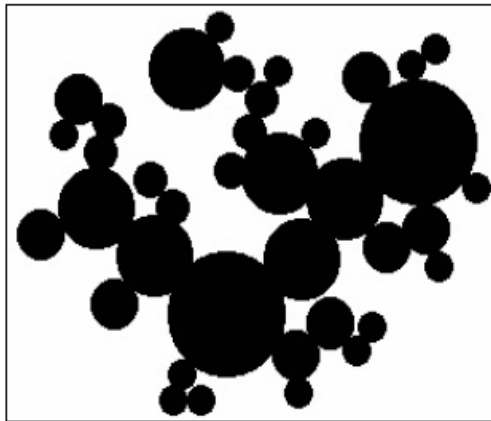

Thinning

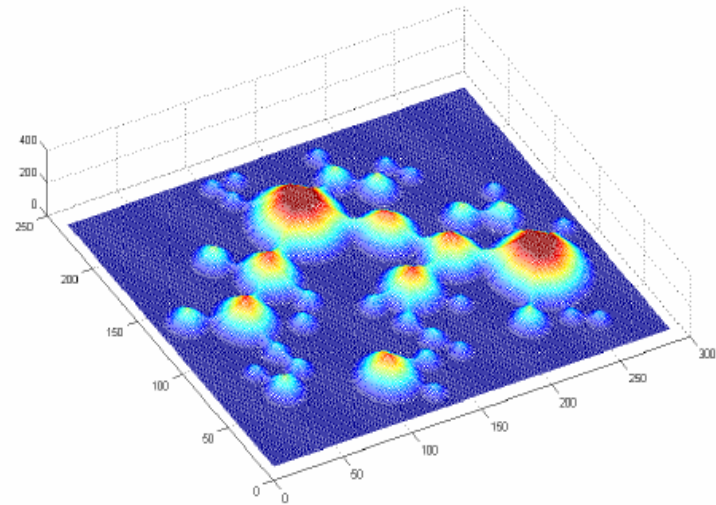

6/6. Euclidean distance maps (EDM)

- Image representing the smallest distance of e/pixel to the background.

A

D

D(3d)

There are several possible definitions for distance

Distance measurements

- Fundamental properties:

$$\forall p, q, r :$$

- $d(p, q) \geq 0$,
 $d(p, q) = 0 \Leftrightarrow p = q$
- $d(p, q) = d(q, p)$
- $d(p, r) \leq d(p, q) + d(q, r)$

$$d([i_1, j_1], [i_2, j_2]) =$$

- Euclidean:

$$\sqrt{(i_1 - i_2)^2 + (j_1 - j_2)^2}$$

- Manhattan:

$$|i_1 - i_2| + |j_1 - j_2|$$

- Chess:

$$\max(|i_1 - i_2|, |j_1 - j_2|)$$

**Euclidean is closest to the real case;
Mosr costly to compute**

Discs: pixels at distance $\leq k$.

Obtaining distance maps

$$f^0[i, j] = B[i, j]$$

$$f^m[i, j] = f^0[i, j] + \min(f^{m-1}[u, v])$$

$$\forall [u, v] : d([u, v], [i, j]) = 1$$

Post-processing

- Reduces the width of the ridges to one pixel
- *Skeletons* , spikes
- Filling holes, removing small breaks, eliminating bridges between ridges etc.
- ***cleanskeleton: removespur, linkbreak, removebridge***

Figure 3.35. The result of eliminating small holes from both the ridges and valleys of the binary image; input image is shown on the left and the output is shown on the right. The filtering is performed by computing the connected components of the image and by removing the components whose area (number of pixels) is smaller than a given threshold.

bwmorph(imcomplement(imReconstruct),'thin', 'Inf');**
%thins the reconstructed image

Singularity and Core Detection

- Poincare Method

$$P_{G,C}(i, j) = \begin{cases} 0^\circ & \text{if } [i, j] \text{ does not belong to any singular region} \\ 360^\circ & \text{if } [i, j] \text{ belongs to a whorl type singular region} \\ 180^\circ & \text{if } [i, j] \text{ belongs to a loop type singular region} \\ -180^\circ & \text{if } [i, j] \text{ belongs to a delta type singular region.} \end{cases}$$

Figure 3.14. The Poincaré index computed over a curve C immersed in a vector field G .

$$P_{G,C}(i, j) = \sum_{k=0..7} \text{angle}(\mathbf{d}_k, \mathbf{d}_{(k+1) \bmod 8})$$

Figure 3.15. Example of computation of the Poincaré index in the 8-neighborhood of points belonging (from the left to the right) to a whorl, loop, and delta singularity, respectively. Note that for the loop and delta examples (center and right), the direction of \mathbf{d}_0 is first chosen upward (to compute the angle between \mathbf{d}_0 and \mathbf{d}_1) and then successively downward (when computing the angle between \mathbf{d}_7 and \mathbf{d}_0).

-Poincare Method

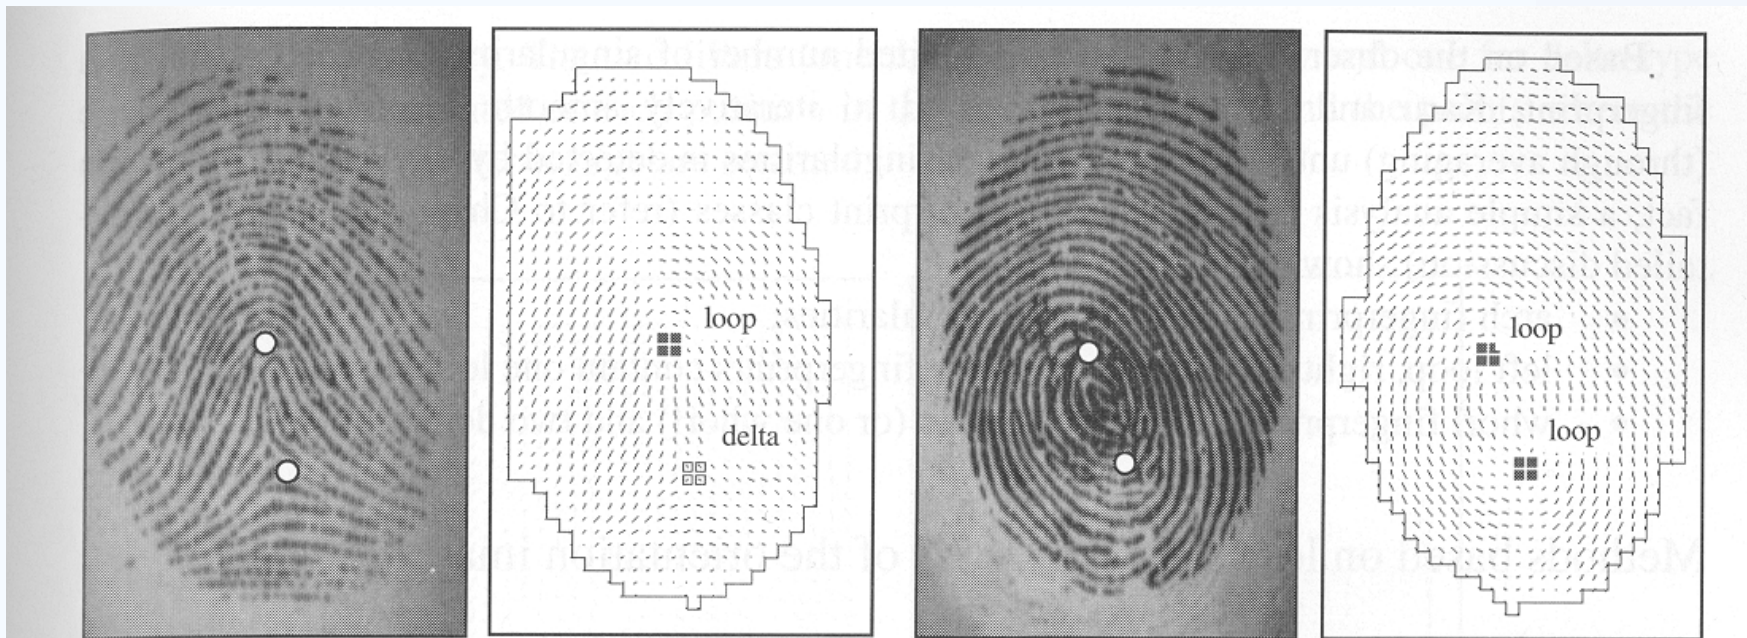

Figure 3.16. Singularity detection by using the Poincaré index method. The elements whose Poincaré index is 180° (loop) or -180° (delta) are enclosed by small boxes. Usually, more than one point (four points in these examples) is found for each singular region: hence, the center of each singular region can be defined as the barycenter of the corresponding points.

Singularity and Core Detection

– Poincare Method

If we know the type of the fingerprint beforehand, false singularities can be eliminated by iteratively smoothing the image with the help of the following observation:

- Arch fingerprints do not contain singularities
- Left loop, right loop and tented arch fingerprints contain one loop and one delta
- Whorl fingerprints contain two loops and two deltas

Figure 3.17. a) A poor quality fingerprint; b) the singularities of the fingerprint in a) are extracted through the Poincaré method (circles highlight the false singularities); c) the orientation image has been regularized and the Poincaré method no longer provides false alarms.

Singularity and Core Detection

- Methods based on local features
 - Orientation histograms at local level (3x3)
 - Irregularity
 - **Fp1 = findsingularitypoint(Fp1);**
 - $d_{ij} = [r_{ij} \cdot \cos 2\theta_{ij}, r_{ij} \cdot \sin 2\theta_{ij}]$

$$\text{irregularity}(i, j) = 1 - \frac{\| \sum_{h=-1..1} \sum_{k=-1..1} \mathbf{d}_{i+h, j+k} \|}{\sum_{h=-1..1} \sum_{k=-1..1} \| \mathbf{d}_{i+h, j+k} \|},$$

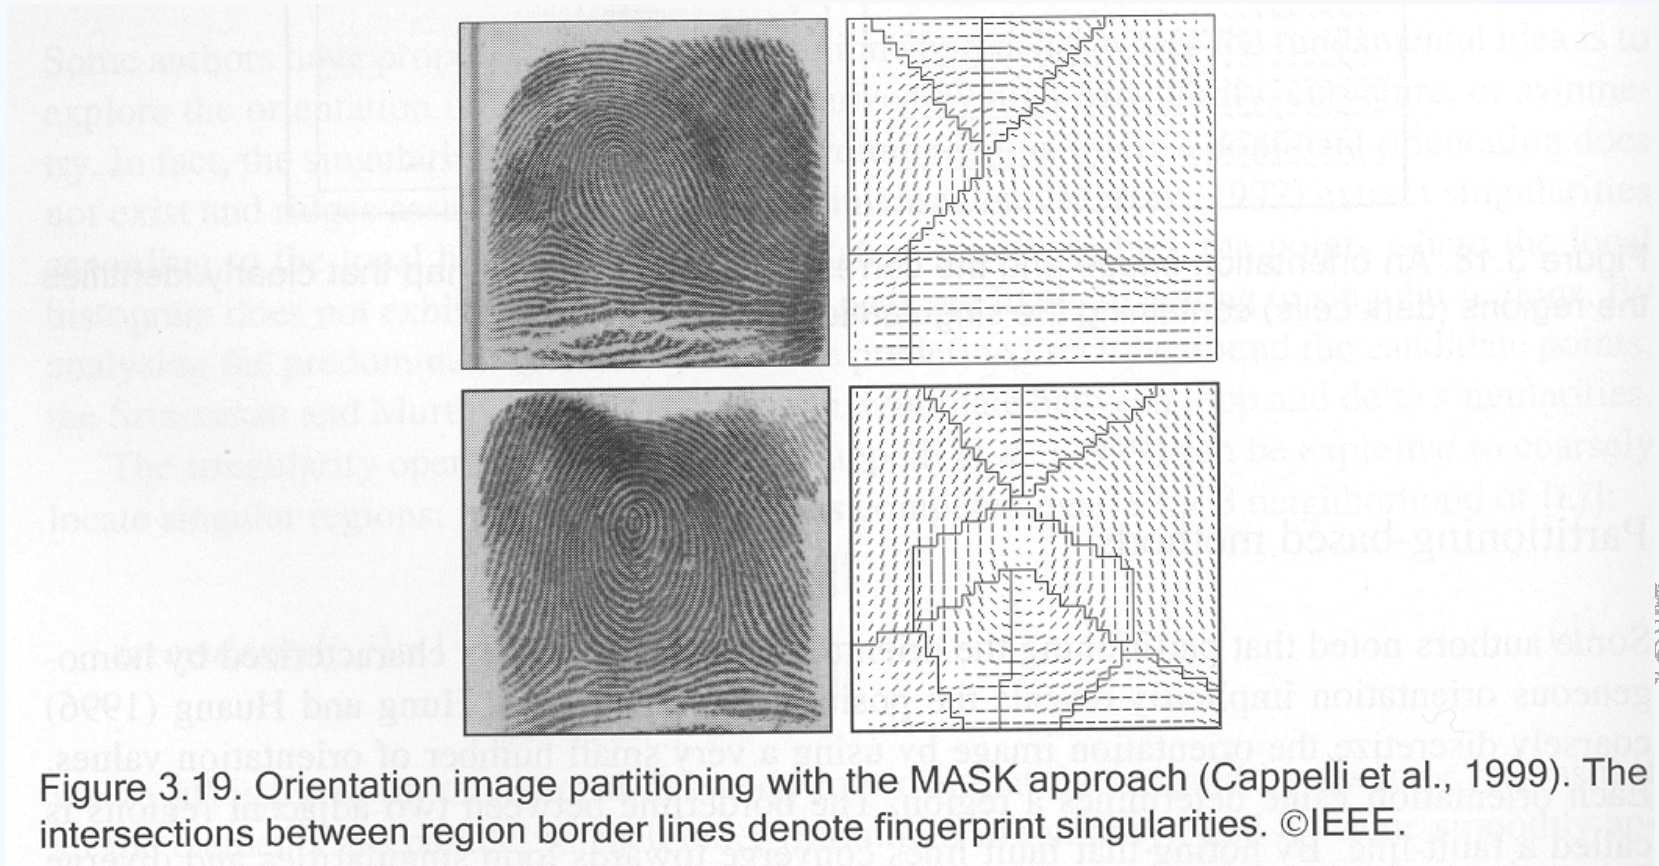

Figure 3.18. An orientation image and the corresponding irregularity map that clearly identifies the regions (dark cells) containing the singularities.

Singularity and Core Detection

–Partitioning based methods

Feature Extraction

Fingerprint image

Fingerprint area, frequency image, and orientation image

Ridge pattern and minutiae points

Feature Extraction Errors

- The **feature extraction algorithms** are imperfect and often introduce measurement errors
- **Errors** may be made during any of the feature extraction stages, e.g., estimation of orientation and frequency images, detection of the number, type, and position of the singularities and minutiae, segmentation of the fingerprint area from background, etc.
- **Aggressive enhancement** algorithms may introduce inconsistent biases that perturb the location and orientation of the reported minutiae from their gray-scale counterparts
- In **low-quality fingerprint images**, the minutiae extraction process may introduce a large number of spurious minutiae and may not be able to detect all the true minutiae

Non-linear distortion

Intra-variability

- **Matching fingerprint images** is an extremely difficult problem, mainly due to the **large variability in different impressions of the same finger (intra-variability)**. The main factors are:
 - **Displacement** (global translation of the fingerprint area)
 - **Rotation**
 - **Partial overlap**
 - **Non-linear distortion:**
 - *the act of sensing maps the three-dimensional shape of a finger onto the two-dimensional surface of the sensor*
 - *skin elasticity*
 - **Pressure and skin condition**
 - **Noise:** introduced by the fingerprint sensing system
 - **Feature extraction errors**

Fingerprint matching

Reference
fingerprint

Test
fingerprint

- Comes the test- and the reference fingerprint from the same finger?
the two fingerprints can be *translated* and *rotated* relative to each other.
- Minutiae based matching: by *direct use of the local structure* of the fingerprints extract common minutiae points.

MATCHING: Approaches

- Correlation-based matching
 - Superimpose images – compare pixels
- Minutiae-based matching
 - Classical Technique – Most popular
 - Compare extracted minutiae
- Ridge Feature-based matching
 - Compare the structures of the ridges
 - Everything else

Fingerprint Matching

- Compare two given fingerprints T, I
 - Return degree of similarity ($0 \rightarrow 1$)
 - Binary Yes/No
- $T \rightarrow$ template, acquired during enrollment
- $I \rightarrow$ Input
- Either input images, or feature vectors (minutiae) extracted from them
- Pressure and Skin condition
 - Pressure, dryness, disease, sweat, dirt, grease, humidity
- Noise
 - Dirt on the sensor
- Feature Extraction Errors
- Many algorithms match high quality images
- Challenge is in low-quality and partial matches
- **20% of the problems (low quality) at FVC2000 caused 80% of the false non-matches**
- Many were correctly identified at FVC2002 though

Correlation-based Techniques

- T and I are images
- Sum of squared Differences
 - $SSD(T,I) = \|T-I\|^2 = (T-I)^T(T-I) = \|T\|^2 + \|I\|^2 - 2T^T I$
 - Difference between pixels
- $\|T\|^2 + \|I\|^2$ are constant under transformation
- Try to maximize correlation – Minimizes difference
 - $CC(T,I) = T^T I$
 - Can't be used because of displacement / rotation

Maximizing Correlation

- $J(\Delta x, \Delta y, \theta)$
 - Transformation of I
 - Rotation around the origin by θ
 - Translation by x, y
- $S(T,I) = \max CC(T, I(\Delta x, \Delta y, \theta))$
 - Try them all – take max

$$S(T, I) = \max_{\Delta x, \Delta y, \theta} CC(T, I(\Delta x, \Delta y, \theta))$$

Correlation Results

Figure 10.5. Original, processed, and absolute value of the impressions of the same finger and the absolute value of the

Minutiae-based Methods

$$\mathbf{m} = \{x, y, \theta\}$$

- Classical Technique
- T, I are feature vectors of minutiae
- Minutiae = (x, y, θ)
- Two minutiae match if
 - Euclidean distance $< r_0$
 - Difference between angles $< \theta_0$
 - Tolerance Boxes
 - r_0
 - θ_0

$$T = \{\mathbf{m}_1, \mathbf{m}_2, \dots, \mathbf{m}_m\}, \quad \mathbf{m}_i = \{x_i, y_i, \theta_i\}, \quad i = 1 \dots m$$
$$I = \{\mathbf{m}'_1, \mathbf{m}'_2, \dots, \mathbf{m}'_n\}, \quad \mathbf{m}'_j = \{x'_j, y'_j, \theta'_j\}, \quad j = 1 \dots n$$

$$sd(\mathbf{m}'_j, \mathbf{m}_i) = \sqrt{(x'_j - x_i)^2 + (y'_j - y_i)^2} \leq r_0, \text{ and}$$

$$dd(\mathbf{m}'_j, \mathbf{m}_i) = \min(|\theta'_j - \theta_i|, 360^\circ - |\theta'_j - \theta_i|) \leq \theta_0.$$

Formulation

- $M''_j = \text{map}(m'_j)$
 - Map applies a geometrical transformation
- $\text{mm}(m''_j, m_i)$ returns 1 if they match
- Matching can be formulated as

$$\text{maximize}_{\Delta x, \Delta y, \theta, P} \sum_{i=1}^m \text{mm}(\text{map}_{\Delta x, \Delta y, \theta}(\mathbf{m}'_{P(i)}), \mathbf{m}_i)$$

- **P is an unknown function which pairs the minutiae**
 - Which minutiae in I corresponds to which in T: **align2**

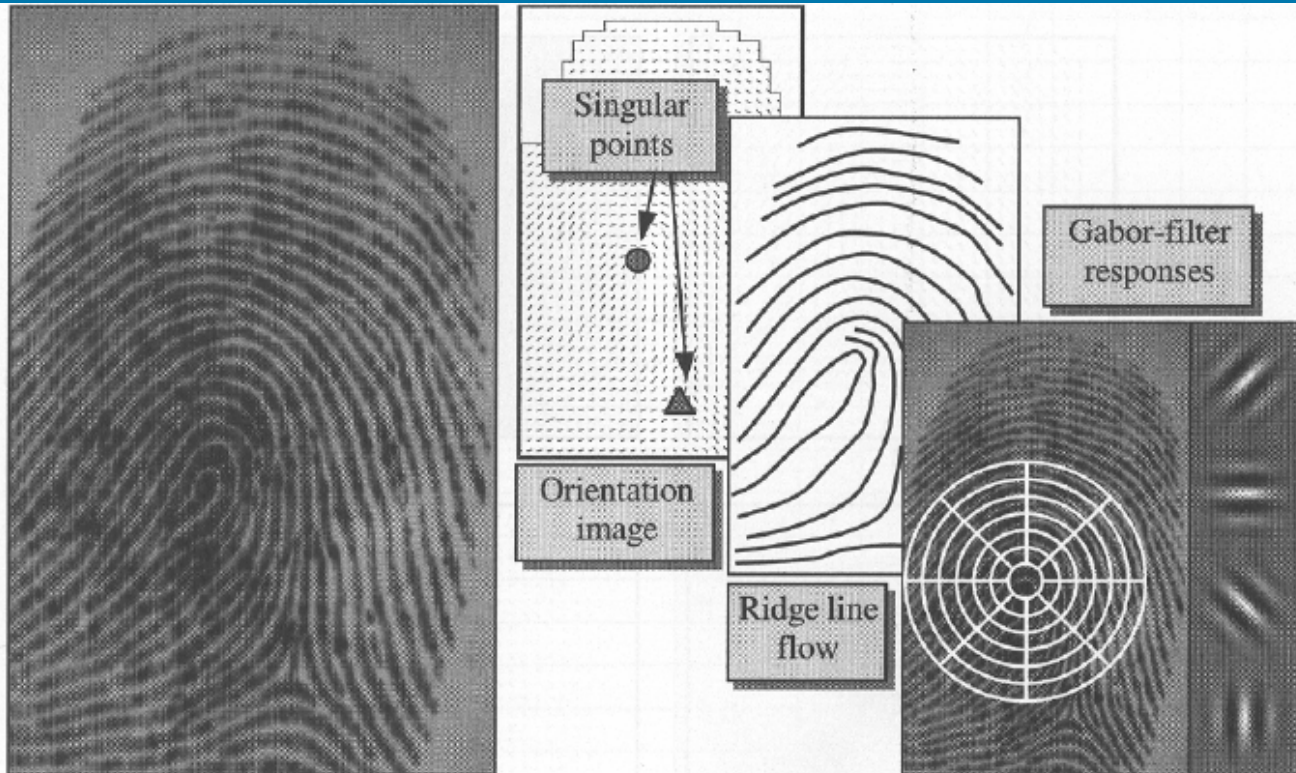

$\text{map}_{\Delta x, \Delta y, \theta}(\mathbf{m}'_j = \{x'_j, y'_j, \theta'_j\}) = \mathbf{m}''_j = \{x''_j, y''_j, \theta'_j + \theta\}$, where

$$\begin{bmatrix} x''_j \\ y''_j \end{bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} x'_j \\ y'_j \end{bmatrix} + \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}$$

$$\text{mm}(\mathbf{m}''_j, \mathbf{m}_i) = \begin{cases} 1 & sd(\mathbf{m}''_j, \mathbf{m}_i) \leq r_0 \text{ and } dd(\mathbf{m}''_j, \mathbf{m}_i) \leq \theta_0 \\ 0 & \text{otherwise.} \end{cases}$$

Ridge feature based matching

Most frequently used features for fingerprint matching:

- Orientation image
- Singular points (loop and delta)
- Ridge line flow
- Gabor filter responses**

Gabor filters

- An input fingerprint image is filtered using 8 Gabor filters all having the same frequency but different orientations (0° , 22.5° , 45° , 67.5° , 90° , 112.5° , 135° , 157.5°)

Local texture analysis

- The fingerprint area of interest is tessellated with respect to the core point
- The local texture information in each sector is decomposed into separate channels by using a Gabor filterbank
- Feature vector:
 - 80 cells (5 bands and 16 sectors)
 - Filterbank of 8 Gabor filters (8 orientations, 1 scale = 1/10 for 500 dpi fingerprint images)
 - Each fingerprint is represented by a $80 \times 8 = 640$ fixed-size feature vector, called the FingerCode
- Computation of average absolute deviation (AAD)

8015

Finger code approach

MatchGaborFeat
