Czech Technical University in Prague

Lecture 08

BE5B99CPL – C Programming Language

Part I

Part 1 – Multithreading Programming

Overview of the Lecture

■ Part 1 – Multithreading Programming

Introduction

Multithreading applications and operating system

Models of Multi-Thread Applications

Synchronization Mechanisms

POSIX Threads

C11 Threads

Debugging

Terminology – Threads

- Thread is an independent execution of a sequence of instructions
 - It is individually performed computational flow
 - Typically a small program that is focused on a particular part*
- Thread is running within the process
 - It shares the same memory space as the process
 - Threads running within the same memory space of the process
- Thread **runtime environment** – each thread has its separate space for variables
 - Thread identifier and space for synchronization variables
 - Program counter (PC) or Instruction Pointer (IP) – address of the performing instruction
 - Indicates where the thread is in its program sequence*
 - Memory space for local variables **stack**

Where Threads Can be Used?

- Threads are lightweight variants of the processes that share the memory space
- There are several cases where it is useful to use threads, the most typical situations are
 - **More efficient usage of the available computational resources**
 - When a process waits for resources (e.g., reads from a periphery), it is blocked, and control is passed to another process
 - Thread also waits, but another thread within the same process can utilize the dedicated time for the process execution
 - Having multi-core processors, we can speed up the computation using more cores simultaneously by **parallel algorithms**
 - **Handling asynchronous events**
 - During blocked i/o operation, the processor can be utilized for other computational
 - One thread can be dedicated for the i/o operations, e.g., per communication channel, another threads for computations

Threads and Processes

Process

- Computational flow
- Has own memory space
- Entity (object) of the OS.
- Synchronization using OS (IPC).
- CPU allocated by OS scheduler
 - Time to create a process

Threads of a process

- Computational flow
- Running in the same memory space of the process
- User or OS entity
- Synchronization by exclusive access to variables
- CPU allocated within the dedicated time to the process
- + Creation is faster than creating a process

Examples of Threads Usage

- **Input/output operations**
 - Input operations can take significant portions of the run-time, which may be mostly some sort of waiting, e.g., for a user input
 - During the communication, the dedicated CPU time can be utilized for computationally demanding operations
- **Interactions with Graphical User Interface (GUI)**
 - Graphical interface requires immediate response for a pleasant user interaction with our application
 - User interaction generates events that affect the application
 - Computationally demanding tasks should not decrease interactivity of the application

Provide a nice user experience with our application

Multi-thread and Multi-process Applications

- **Multi-thread application**
 - + Application can enjoy higher degree of interactivity
 - + Easier and faster communications between the threads using the same memory space
 - It does not directly support scaling the parallel computation to distributed computational environment with different computational systems (computers)
- Even on single-core single-processor systems, multi-thread application may better utilize the CPU

Threads in the Operating System

- Threads are running within the process, but regarding the implementation, threads can be:
 - In the **user space of the process** – threads are implemented by a user specified library
 - Threads do not need a special support from the OS
 - Threads are scheduled by the local scheduler provided by the library
 - Threads typically cannot utilize more processors (multi-core)
 - OS entities** that are scheduled by the system scheduler
 - It may utilized multi-core or multi-processors computational resources

Threads in the User Space

Threads as Operating System Entities

User Threads vs Operating System Threads

User Threads

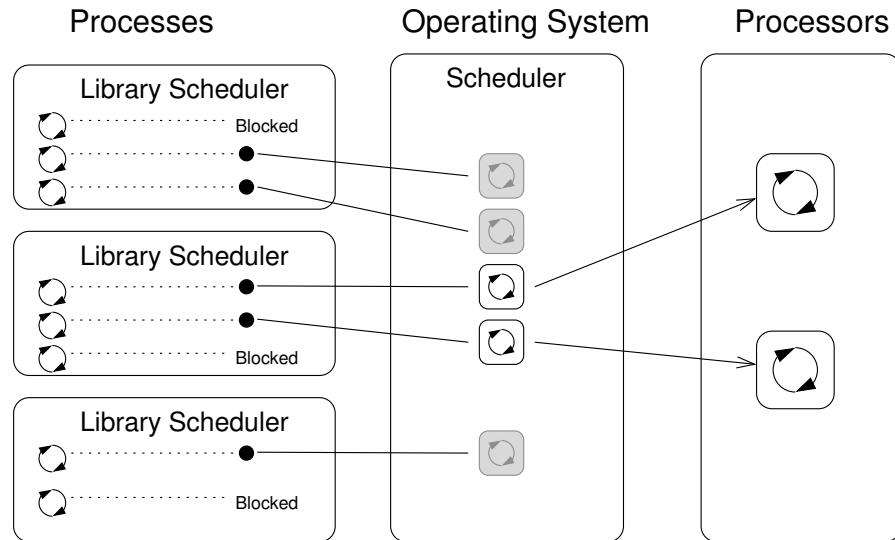

- + Do not need support of the OS
- + Creation does need (expensive) system call
- Execution priority of threads is managed within the assigned process time
- Threads cannot run simultaneously (pseudo-parallelism)

Operating System Threads

- + Threads can be scheduled in competition with all threads in the system
- + Threads can run simultaneously (on multi-core or multi-processor system – true parallelism)
- Thread creation is a bit more complex (system call)

A high number of threads scheduled by the OS may increase overhead. However, modern OS are using O(1) schedulers – scheduling a process is an independent on the number of processes. Scheduling algorithms based on complex heuristics.

Combining User and OS Threads

Typical Multi-Thread Applications

- **Servers** – serve multiple clients simultaneously. It may require access to shared resources and many i/o operations.
- **Computational application** – having multi-core or multi-processor system, the application runtime can be decreased by using more processors simultaneously
- **Real-time applications** – we can utilize specific schedulers to meet real-time requirements. Multi-thread application can be more efficient than complex asynchronous programming; a thread waits for the event vs. explicit interrupt and context switching

When to use Threads

- Threads are advantageous whenever the application meets any of the following criteria:
 - It consists of several independent tasks
 - It can be blocked for a certain amount of time
 - It contains a computationally demanding part (while it is also desirable to keep interactivity)
 - It has to promptly respond to asynchronous events
 - It contains tasks with lower and higher priorities than the rest of the application
 - The main computational part can be speeded up by a parallel algorithm using multi-core processors

Models of Multithreading Applications

- Models address creation and division of the work to particular threads
 - **Boss/Worker** – the main thread control division of the work to other threads
 - **Peer** – threads run in parallel without specified manager (boss)
 - **Pipeline** – data processing by a sequence of operations
 - *It assumes a long stream of input data and particular threads works in parallel on different parts of the stream*

Boss/Worker Model

Example – Boss/Worker

```

1 // Boss
2 while(1) {
3     switch(getRequest()) {
4         case taskX :
5             create_thread(taskX);
6             break;
7         case taskY:
8             create_thread(taskY);
9             break;
10    }
11 }

1 // Task solvers
2 taskX()
3 {
4     solve the task //
5     synchronized usage of
6     shared resources
7     done;
8 }
9 taskY()
10 {
11    solve the task //
12    synchronized usage of
13    shared resources
14    done;
15 }

```

Boss/Worker Model – Roles

- The main thread is responsible for managing the requests. It works in a cycle:
 1. Receive a new request
 2. Create a thread for serving the particular request
Or passing the request to the existing thread
 3. Wait for a new request
- The output/results of the assigned request can be controlled by
 - Particular thread (worker) solving the request
 - The main thread using synchronization mechanisms (e.g., event queue)

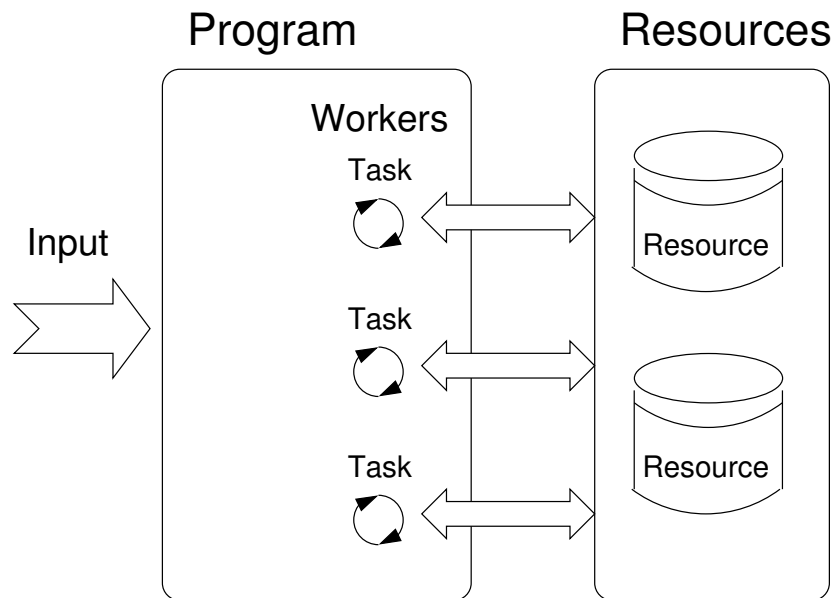

Thread Pool

- The main thread creates threads upon new request is received
- The overhead with creation of new threads can be decreased by the **Thread Pool** with already created threads
- The created threads wait for new tasks

- Properties of the thread pool needs to consider
 - Number of pre-created threads
 - Maximal number of the request in the queue of requests
 - Definition of the behavior if the queue is full and none of the threads is available
E.g., block the incoming requests

Peer Model

Peer Model Properties and Example

- It does not contain the main thread
- The first thread creates all other threads and then
 - It becomes one of the other threads (equivalent)
 - It suspends its execution and waits to other threads
- Each thread is responsible for its input and output
- Example:

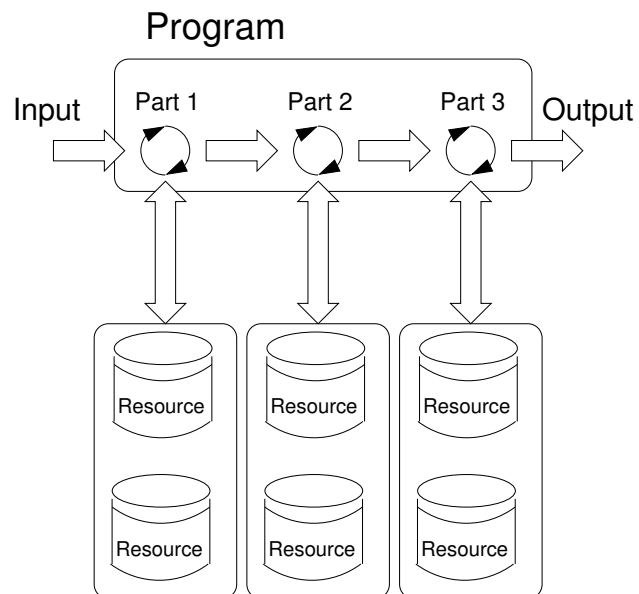

```

1 // 1st thread
2 {
3   create_thread(task1);
4   create_thread(task2);
5   :
6   :
7   start all threads;
8   wait to all threads;
9 }

1 // Task solvers
2 task1()
3 {
4   wait to be executed
5   solve the task // synchronized
6   usage of shared resources
7   done;
8 }
9 task2()
10 {
11   wait to be executed
12   solve the task // synchronized
13   usage of shared resources
14   done;
15 }

```

Data Stream Processing – Pipeline

Pipeline Model – Properties and Example

- A long input stream of data with a sequence of operations
 - Each input data unit must be processed by all parts of the processing pipeline
- At a particular time, different input data units are processed by individual processing parts – the input units must be independent

```

main()
{
  create_thread(stage1);
  create_thread(stage2);
  ...
  wait // for all pipeline;
}

stage1()
{
  while(input) {
    get next program input;
    process input;
    pass result to next the stage;
  }
}

stage2()
{
  while(input) {
    get next input from thread;
    process input;
    pass result to the next stage;
  }
  ...
  stageN()
  {
    while(input) {
      get next input from thread;
      process input;
      pass result to output;
    }
  }
}

```

Producer–Consumer Model

- Passing data between units can be realized using a memory buffer
 - Or just a buffer of references (pointers) to the particular data units*
 - Producer – thread that passes data to other thread
 - Consumer – thread that receives data from other thread
- Access to the buffer must be synchronized (exclusive access)

Using the buffer does not necessary mean the data are copied

Mutex – A Locker of Critical Section

- Mutex is shared variable accessible from particular threads
- Basic operations that threads may performed on the mutex
 - **Lock** the mutex (acquired the mutex to the calling thread)
 - If the mutex cannot be acquired by the thread (because another thread holds it), the thread is **blocked and waits for mutex release**
 - **Unlock** the already acquired mutex
 - If there is one or several threads trying to acquired the mutex (by calling lock on the mutex), one of the thread is selected for mutex acquisition

Synchronization Mechanisms

- Synchronization of threads uses the same principles as synchronization of processes
 - Because threads share the memory space with the process, the main communication between the threads is through the memory and (global) variables
 - The crucial is the control of access to the same memory
 - **Exclusive access** to the **critical section**
- Basic synchronization primitives are
 - **Mutexes/Lockers** for exclusive access to critical section (mutexes or spinlocks)
 - **Condition variable** synchronization of threads according to the value of the shared variable

A sleeping thread can be awakened by the signaling from another thread

Example – Mutex and Critical Section

- Lock/Unlock access to the critical section via `drawingMtx` mutex

```

1 void add_drawing_event(void)
2 {
3     Tcl_MutexLock(&drawingMtx);
4     Tcl_Event * ptr = (Tcl_Event*)Tcl_Alloc(sizeof(Tcl_Event));
5     ptr->proc = MyEventProc;
6     Tcl_ThreadQueueEvent(guiThread, ptr, TCL_QUEUE_TAIL);
7     Tcl_ThreadAlert(guiThread);
8     Tcl_MutexUnlock(&drawingMtx);
9 }

```

Example of using thread support from the TCL library

- Example of using a concept of `ScopedLock`

```

1 void CCanvasContainer::draw(cairo_t *cr)
2 {
3     ScopedLock lk(mtx);
4     if (drawer == 0) {
5         drawer = new CCanvasDrawer(cr);
6     } else {
7         drawer->setCairo(cr);
8     }
9     manager.execute(drawer);
10 }

```

The ScopedLock releases (unlocks) the mutex once the local variable lk is destroyed at the end of the function call

Generalized Models of Mutex

- Recursive – the mutex can be locked multiple times by the same thread
- Try – the lock operation immediately returns if the mutex cannot be acquired
- Timed – limit the time to acquired the mutex
- *Spinlock* – the thread repeatedly checks if the lock is available for the acquisition

Thread is not set to blocked mode if lock cannot be acquired

Condition Variable

- **Condition variable** allows signaling the thread from another thread
- The concept of **condition variable** allows the following synchronization operations
 - Wait – the variable has been changed/notified
 - Timed waiting for signal from other thread
 - Signaling other thread waiting for the condition variable
 - Signaling all threads waiting for the condition variable

All threads are awakened, but the access to the condition variable is protected by the mutex that must be acquired and only one thread can lock the mutex

Spinlock

- Under certain circumstances it may be advantageous to do not block the thread during acquisition of the mutex (lock), e.g.,
 - Performing a simple operation on the shared data/variable on the system with true parallelism (using multi-core cpu)
 - Blocking the thread, suspending its execution and passing the allocated CPU time to other thread may results a significant overhead
 - Other threads quickly perform other operation on the data and thus, the shared resource would be quickly accessible
- During the locking, the thread actively tests if the lock is free

It "wastes" the cpu time that can be used for productive computation elsewhere, but here it is desirable and intentional
- Similarly to a semaphore such a test has to be perform by TestAndSet instruction at the CPU level
- **Adaptive mutex** combines both approaches to use the **spinlocks** to access resources locked by currently running thread and block/sleep if such a thread is not running

It does not make sense to use spinlocks on single-processor systems with pseudo-parallelism

Example – Condition Variable

- Example of using condition variable with lock (mutex) to allow exclusive access to the condition variable from different threads

```
Mutex mtx; // shared variable for both threads
ConditionVariable cond; // shared condition variable

// Thread 1                                // Thread 2
Lock(mtx);                                  Lock(mtx);
// Before code, wait for Thread 2          ... // Critical section
CondWait(cond, mtx); // wait for cond      // Signal on cond
... // Critical section                    CondSignal(cond, mtx);
UnLock(mtx);                               UnLock(mtx);
```

Parallelism and Functions

- Regarding the parallel execution, functions called multiple times can be
 - **Reentrant** – at a single moment, the same function can be executed multiple times simultaneously
 - **Thread-Safe** – the function can be called by multiple threads simultaneously
- To achieve these properties
 - **Reentrant function** does not write to static data and does not work with global data
 - **Thread-safe function** strictly access to global data using synchronization primitives

POSIX Thread Functions (pthread)

- POSIX threads library (`<pthread.h>` and `-lpthread`) is a set of functions to support multithreading programming
- The basic types for threads, mutexes, and condition variables are
 - `pthread_t` – type for representing a thread
 - `pthread_mutex_t` – type for mutex
 - `pthread_cond_t` – type for condition variable
- The thread is created by `pthread_create()` function call, which immediately executes the new thread as a function passed as a pointer to the function

The thread calling the creation continues with the execution
- A thread may wait for other thread by `pthread_join()`
- Particular mutex and condition variables has to be initialized using the library calls

Note, initialized shared variables before threads are created

 - `pthread_mutex_init()` – initialize mutex variable
 - `pthread_cond_init()` – initialize condition variable

Additional attributes can be set, see documentation

Main Issues with Multithreading Applications

- The main issues/troubles with multiprocessing application are related to synchronization
 - **Deadlock** – a thread wait for a resource (mutex) that is currently locked by other thread that is waiting for the resource (thread) already locked by the first thread
 - **Race condition** – access of several threads to the shared resources (memory/variables) and at least one of the threads does not use the synchronization mechanisms (e.g., critical section)

A thread reads a value while another thread is writing the value. If Reading/writing operations are not atomic, data are not valid.

POSIX Threads – Example 1/10

- Create an application with three active threads for
 - Handling user input – function `input_thread()`
 - User specifies a period output refresh of by pressing dedicated keys
 - Refresh output – function `output_thread()`
 - Refresh output only when the user interacts with the application or the alarm is signaling the period has been passed
 - Alarm with user defined period – function `alarm_thread()`
 - Refresh the output or do any other action
- For simplicity the program uses `stdin` and `stdout` with thread activity reporting to `stderr`
- Synchronization mechanisms are demonstrated using
 - `pthread_mutex_t mtx` – for exclusive access to `data_t data`
 - `pthread_cond_t cond` – for signaling threads

The shared data consists of the current period of the alarm (`alarm_period`), request to quit the application (`quit`), and number of alarm invocations (`alarm_counter`)

POSIX Threads – Example 2/10

- Including header files, defining data types, declaration of global variables

```

1  #include <stdio.h>
2  #include <stdlib.h>
3  #include <stdbool.h>
4  #include <termios.h>
5  #include <unistd.h> // for STDIN_FILENO
6  #include <pthread.h>
7
8  #define PERIOD_STEP 10
9  #define PERIOD_MAX 2000
10 #define PERIOD_MIN 10
11
12 typedef struct {
13     int alarm_period;
14     int alam_counter;
15     bool quit;
16 } data_t;
17
18 pthread_mutex_t mtx;
19 pthread_cond_t cond;

```

POSIX Threads – Example 3/10

- Functions prototypes and initialize of variables and structures

```

21 void call_termios(int reset); // switch terminal to raw mode
22 void* input_thread(void*);
23 void* output_thread(void*);
24 void* alarm_thread(void*);
25
26 // - main function -----
27 int main(int argc, char *argv[])
28 {
29     data_t data = { .alarm_period = 100, .alam_counter = 0, .quit = false };
30
31     enum { INPUT, OUTPUT, ALARM, NUM_THREADS }; // named ints for the threads
32     const char *threads_names[] = { "Input", "Output", "Alarm" };
33
34     void* (*thr_functions[])(void*) = { // array of thread functions
35         input_thread, output_thread, alarm_thread
36     };
37
38     pthread_t threads[NUM_THREADS]; // array for references to created threads
39     pthread_mutex_init(&mtx, NULL); // init mutex with default attr.
40     pthread_cond_init(&cond, NULL); // init cond with default attr.
41
42     call_termios(0); // switch terminal to raw mode

```

POSIX Threads – Example 4/10

- Create threads and wait for terminations of all threads

```

44     for (int i = 0; i < NUM_THREADS; ++i) {
45         int r = pthread_create(&threads[i], NULL, thr_functions[i], &data);
46         fprintf(stderr, "Create thread '%s' %s\n", threads_names[i], ( r == 0
47             ? "OK" : "FAIL" ) );
48     }
49
50     int ex;
51     for (int i = 0; i < NUM_THREADS; ++i) {
52         fprintf(stderr, "Call join to the thread %s\n", threads_names[i]);
53         int r = pthread_join(threads[i], (void*)&ex);
54         fprintf(stderr, "Joining the thread %s has been %s - exit value %i\n"
55             , threads_names[i], (r == 0 ? "OK" : "FAIL"), ex);
56     }
57
58     call_termios(1); // restore terminal settings
59     return EXIT_SUCCESS;

```

POSIX Threads – Example 5/10 (Terminal Raw Mode)

- Switch terminal to raw mode

```

60 void call_termios(int reset)
61 {
62     static struct termios tio, tioOld; // use static to preserve the initial
63     settings
64     tcgetattr(STDIN_FILENO, &tio);
65     if (reset) {
66         tcsetattr(STDIN_FILENO, TCSANOW, &tioOld);
67     } else {
68         tioOld = tio; //backup
69         cfmakeraw(&tio);
70         tio.c_lflag &= ~ECHO; // assure echo is disabled
71         tio.c_oflag |= OPOST; // enable output postprocessing
72         tcsetattr(STDIN_FILENO, TCSANOW, &tio);
73     }

```

The caller is responsible for appropriate calling the function, e.g., to preserve the original settings, the function must be called with the argument 0 only once

POSIX Threads – Example 6/10 (Input Thread 1/2)

```

73 void* input_thread(void* d)
74 {
75     data_t *data = (data_t*)d;
76     static int r = 0;
77     int c;
78     while (( c = getchar()) != 'q') {
79         pthread_mutex_lock(&mtx);
80         int period = data->alarm_period; // save the current period
81         // handle the pressed key detailed in the next slide
82     ....
83     if (data->alarm_period != period) { // the period has been changed
84         pthread_cond_signal(&cond); // signal the output thread to refresh
85     }
86     data->alarm_period = period;
87     pthread_mutex_unlock(&mtx);
88 }
89 r = 1;
90 pthread_mutex_lock(&mtx);
91 data->quit = true;
92 pthread_cond_broadcast(&cond);
93 pthread_mutex_unlock(&mtx);
94 fprintf(stderr, "Exit input thread %lu\n",
    (unsigned long)pthread_self());
95 return &r;

```

POSIX Threads – Example 7/10 (Input Thread 2/2)

- input_thread() – handle the user request to change period

```

68 switch(c) {
69     case 'r':
70         period -= PERIOD_STEP;
71         if (period < PERIOD_MIN) {
72             period = PERIOD_MIN;
73         }
74         break;
75     case 'p':
76         period += PERIOD_STEP;
77         if (period > PERIOD_MAX) {
78             period = PERIOD_MAX;
79         }
80         break;
81 }

```

POSIX Threads – Example 8/10 (Output Thread)

```

97 void* output_thread(void* d)
98 {
99     data_t *data = (data_t*)d;
100     static int r = 0;
101     bool q = false;
102     while (!q) {
103         pthread_mutex_lock(&mtx);
104         pthread_cond_wait(&cond, &mtx); // wait4next event
105         q = data->quit;
106         printf("\rAlarm time: %10i Alarm counter: %10i", data->alarm_period,
107             data->alam_counter);
108         fflush(stdout);
109         pthread_mutex_unlock(&mtx);
110     }
111     fprintf(stderr, "Exit output thread %lu\n", (unsigned long)pthread_self());
112     return &r;

```

POSIX Threads – Example 9/10 (Alarm Thread)

```

114 void* alarm_thread(void* d)
115 {
116     data_t *data = (data_t*)d;
117     static int r = 0;
118     pthread_mutex_lock(&mtx);
119     bool q = data->quit;
120     useconds_t period = data->alarm_period * 1000; // alarm_period is in ms
121     pthread_mutex_unlock(&mtx);
122
123     while (!q) {
124         usleep(period);
125         pthread_mutex_lock(&mtx);
126         q = data->quit;
127         data->alam_counter += 1;
128         period = data->alarm_period * 1000; // update the period is it has been
129         // changed
130         pthread_cond_broadcast(&cond);
131         pthread_mutex_unlock(&mtx);
132     }
133     fprintf(stderr, "Exit alarm thread %lu\n", (unsigned long)pthread_self());
134     return &r;

```

POSIX Threads – Example 10/10

- The example program `lec08/threads.c` can be compiled and run

```
clang -c threads.c -std=gnu99 -O2 -pedantic -Wall -o threads.o
clang threads.o -lpthread -o threads
```

- The period can be changed by 'r' and 'p' keys.
- The application is terminated after pressing 'q'

```
./threads
Create thread 'Input' OK
Create thread 'Output' OK
Create thread 'Alarm' OK
Call join to the thread Input
Alarm time:      110   Alarm counter:      20Exit input thread
750871808
Alarm time:      110   Alarm counter:      20Exit output thread
750873088
Joining the thread Input has been OK - exit value 1
Call join to the thread Output
Joining the thread Output has been OK - exit value 0
Call join to the thread Alarm
Exit alarm thread 750874368
Joining the thread Alarm has been OK - exit value 0
```

`lec08/threads.c`

C11 Threads Example

- The previous example `lec08/threads.c` implemented with C11 threads is in `lec08/threads-c11.c`

```
clang -std=c11 threads-c11.c -lstdthreads -o threads-c11
./threads-c11
```

- Basically, the function calls are similar with different names and minor modifications

- `pthread_mutex_*`() → `mxt_*`()
- `pthread_cond_*`() → `cnd_*`()
- `pthread_*`() → `thrd_*`()
- Thread body functions return int value
- There is not `pthread_self()` equivalent
- `thrd_t` is implementation dependent
- Threads, mutexes, and condition variables are created/initialized without specification particular attributes

Simplified interface

- The program is linked with the `-lstdthreads` library

`lec08/threads-c11.c`

C11 Threads

- C11 provides a “wrapper” for the POSIX threads

E.g., see <http://en.cppreference.com/w/c/thread>

- The library is `<threads.h>` and `-lstdthreads`

- Basic types

- `thrd_t` – type for representing a thread
- `mtx_t` – type for mutex
- `cnd_t` – type for condition variable

- Creation of the thread is `thrd_create()` and the thread body function has to return an `int` value

- `thrd_join()` is used to wait for a thread termination

- Mutex and condition variable are initialized (without attributes)

- `mtx_init()` – initialize mutex variable
- `cnd_init()` – initialize condition variable

How to Debug Multi-Thread Applications

- The best tool to debug a multi-thread application is

to do not need to debug it

- It can be achieved by discipline and a prudent approach to shared variables
- Otherwise a debugger with a minimal set of features can be utilized

Debugging Support

- Desired features of the debugger

- List of running threads
- Status of the synchronization primitives
- Access to thread variables
- Break points in particular threads

lldb – <http://lldb.llvm.org>; gdb – <https://www.sourceware.org/gdb>
cgdb, ddd, kgdb, Code::Blocks or Eclipse, Kdevelop, Netbeans, CLion

SlickEdit – <https://www.slickedit.com>; TotalView – <http://www.roguewave.com/products-services/totalview>

- **Logging** can be more efficient to debug a program than manual debugging with manually set breakpoints

- Deadlock is mostly related to the order of locking
- Logging and analyzing access to the lockers (mutex) can help to find a wrong order of the thread synchronizing operations

Comments – Deadlock

- Deadlocks are related to the mechanisms of synchronization
 - Deadlock is much easier to debug than the race condition
 - Deadlock is often the *mutex deadlock* caused by the order of multiple mutex locking
 - **Mutex deadlock can cannot occur** if at any moment, each thread has (or it is trying to acquire) **at most a single mutex**
 - It is **not recommended to call functions with a locked mutex**, especially if the function is attempting to lock another mutex
 - **It is recommended to lock the mutex for the shortest possible time**

Comments – Race Condition

- Race condition is typically caused by a lack of synchronization

- It is worth of remember that

- **Threads are asynchronous**

Do not rely that a code execution is synchronous on a single processor system

- **When writing multi-threaded applications assume that the thread can be interrupted or executed at any time**

Parts of the code that require a particular execution order of the threads needs synchronization

- **Never assume that a thread waits after it is created**

It can be started very soon and usually much sooner than you can expect

- **Unless you specify the order of the thread execution, there is not such order**

“Threads are running in the worst possible order”. Bill Gallmeister

Summary of the Lecture

Topics Discussed

- Multithreading programming
 - Terminology, concepts, and motivations for multithreading programming
 - Models of multi-threaded applications
 - Synchronization mechanisms
 - POSIX and C11 thread libraries

Example of an application

- Comments on debugging and multi-thread issues with the race condition and deadlock

- **Next: ANSI C, C99, C11 – differences and extensions**
