Reference Tracking System for a Mobile Skid Steer Robot

Vladimír Kubelka, Vladimír Burian, Přemysl Kafka

May 9, 2012

Abstract

The reference tracking system was developed for the NiFTI robot odometry system performance verification as a "Prace v tymu a jeji organizace A3M99PTO" course semester project. It uses a single video camera to track the robot movement in a plane. A distinct colored marker must be attached to the robot to be tracked. The tracker can also determine the robot azimuth given the target contains two differently colored areas. This report serves as a user manual demonstrating the system usage and will lead the reader through the entire process.

1 Introduction

The aim of the project was to design and create a video camera reference tracking system. The system would determine position and heading of a mobile robot using image processing methods. The specifications were:

- an easy-to-install camera setup
- usable outdoor, independent on light conditions
- supporting the robot odometry system including synchronization

All the specifications were fulfilled reaching localization accuracy (15 ± 13) cm and heading accuracy (3.8 ± 2.7) degrees (the heading accuracy depends on the robot distance, the position accuracy applies for the whole experiment area).

2 The experiment

2.1 The experimental setup

Before describing the experiment setup steps, this is a necessary equipment list:

- video camera
- stable tripod or equivalent camera support
- measuring tape
- paper sticks (to mark a certain point on the ground)
- colored target (will be described)

The robot must be equipped with a colored target (Fig. 1 or 2 or similar, the color is arbitrary, but unique in the scene). Since the experiment will be recorded using a video camera probably not positioned directly above the robot (ideal setup), the target should be visible from any direction from a certain height above it (recording from a second floor window has been found sufficient).

The video camera, as mentioned before, should be positioned as high as possible. It must have the whole experiment scene in its view and must not be moved after the calibration points were recorded. We recommend some heavy-duty tripod.

Figure 1: A simple 2D tracking target.

2.2 The calibration

To transform the tracked image data into the world coordinates, a set of at least 4 points must be recorded. A short video (several seconds) - NOT a photograph - of the robot standing on each calibration point should be recorded. World coordinates of the calibration points must be known, thus, some measuring tape, paper and pencil is required. It is suitable to create some solid marks at the experimental area to save some time.

IMPORTANT: There must be at least 4 calibration points of which any 3 must not lay in a line - for example, a square fulfills this condition. Having these 4 points, other may be added to increase the homography transformation accuracy. The calibration points should cover the whole experiment area.

2.3 The robot odometry system

The reference system can be used for other purposes, but the original one is performance verification and tuning of the robot odometry system. Also,

Figure 2: A 2D + azimuth tracking target.

the reference system expects one of the log files created by the odometry system to be provided. The steps to launch the robot odometry system are as follows:

- 1. Turn the robot on.
- 2. Log in using a ssh shell connection.
- 3. Launch the basic set of nodes by typing "roslaunch nifti_drivers_launchers ugv.launch"
- 4. Verify the logging of the odometry data is enabled by checking the appropriate value in the "nifti_vision/inso/launch/inso.launch" file. Make sure the logging into the "vpa" file is enabled:

```
<param name="inso_vpa" value="$(find inso)/logger/inso_vpa" />
<param name="inso_logging" value="true" />
```

5. Launch the odometry system: "roslaunch inso inso.lauch"

6. Wait until the "Calibration finished" message appears before moving the robot.

Every time the odometry system (*inso*) is launched, a new log file is created in the "nifti_vision/inso/logger" folder (for detailed description, see the *inso* node documentation). So, instead of recording one long odometry track, the user can divide the experiment into several shorter ones. Before the tracked experiment is performed, a set of calibration points must be recorded. It is not necessary for the odometry system to run during the calibration sequence recording.

2.4 The experiment

Having at least 4 calibration points, experiments may be performed. A proven sequence of operations follows:

- 1. Launch the "ugv.launch".
- 2. Navigate the robot to the initial position.
- 3. Launch the odometry system "inso.launch". Wait for the "calibration finished" message to appear.
- 4. Start recording the video. Do not move the camera when pushing the trigger.
- 5. Perform the experiment.
- 6. Stop recording the video.
- 7. Shut down the odometry system.
- 8. Repeat steps 2 7 as many times as desired.
- 9. Shut down the "ugv.launch".
- 10. Store all the new log files created in the robot "nifti_vision/inso/logger" folder with the recorded videos for further processing.
- 11. Turn the robot off.

The result of an experiment should be :

- A set of short videos with calibration points.
- World coordinates of the calibration points.

- Videos of the experiments.
- "Vpa" log files from the odometry system.

If you do have these, you can proceed to the next chapter.

3 The tracking software part

3.1 The software prerequisites and outputs

The tracking software expects you to have:

- several short videos containing the robot positioned on the calibration points
- world coordinates of the calibration points
- videos containing the experiments
- the "inso_vpa_....csv" file for each experiment

It will load the calibration points (its image and world coordinates), track the robot movement during the experiments, determine its path in the world coordinates and finally synchronize it with the robot internal odometry track provided in the "vpa" file. In the end, the software will create an "inso_track_...scv" file with time, world coordinates and heading saved using a standard csv format (with comma as a delimiter).

3.2 Step-by-step instructions

The user interface is implemented in the MathWorks MATLAB environment and uses GUI elements as well as the MATLAB console (for entering text parameters). To launch the software, copy it into a desired folder in your MATLAB file structure and set the active MATLAB path to the folder containing the "run_the_tracker.m" file. Then, type "run_the_tracker" and the software will start.

A GUI window will appear (Fig. 4) asking the user to select a working folder for the tracked experiments. It is possible to create a new one if needed, or to select one to continue working in an existing one. This folder serves as place to save intermediate results (calibration data common for the entire experiment or tracked paths).

Subsequently, the user is asked whether he wants to perform a new calibration (creating point pairs for homography transformation) or to load an existing one (Fig. 5). In the case of the new calibration, the user enters a number of calibration points he can provide (Fig. 6) which is at least 4. The order of the calibration pairs entered is arbitrary. The creation of a calibration pair is following: The user selects a video file with the robot positioned on the calibration point and one frame from the video appears. The cursor becomes a cross and the user marks the center of the colored marker (Fig.

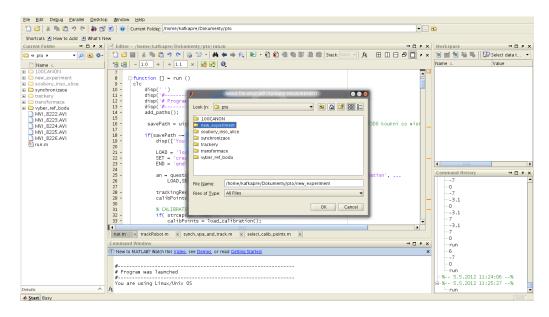

Figure 3: Selection of the experiment folder for the data to be saved to.

7). Then, the world coordinates of the point are entered using the MATLAB console (Fig. 8).

Figure 4: Selection of the experiment folder for the data to be saved to.

The tracking process follows. The user decides if he wants to create a new track or if an existing one will be loaded (Fig. 9). There is an option whether a simple 2D track shall be created or if an azimuth should be detected

Figure 5: Create a new set of calibration points or load an existing one.

Figure 6: The user enters the number of the calibration points he can provide.

(requires the special colored target during the experiment) (Fig. 10). The tracking is similar for both choices; the user marks the whole colored target or two colored regions in the case of an azimuth tracking (Fig. 11 and 12). Because the target will be probably small compared to the entire scene, the user can zoom to the target before the selection. The selection is confirmed by a double-click.

After the tracking process (Fig. 13) finishes, the resulting plot is shown in the picture as well as in the world coordinates (Fig. 14 and 15). The result is synchronized with the robot odometry system by selecting the appropriate "inso_vpa...csv" file and following the GUI message instructions. The synchronization needs the beginning and the end of the experiment to be marked in the tracked data as well as in the odometry data (Fig. 16). When done, a "inso_track...csv" file is created in the experiment folder containing the resulting reference data.
