Computer Architectures

Number Representation and Computer Arithmetics
Pavel Píša, Richard Šusta
Michal Štepanovský, Miroslav Šnorek

Czech Technical University in Prague, Faculty of Electrical Engineering

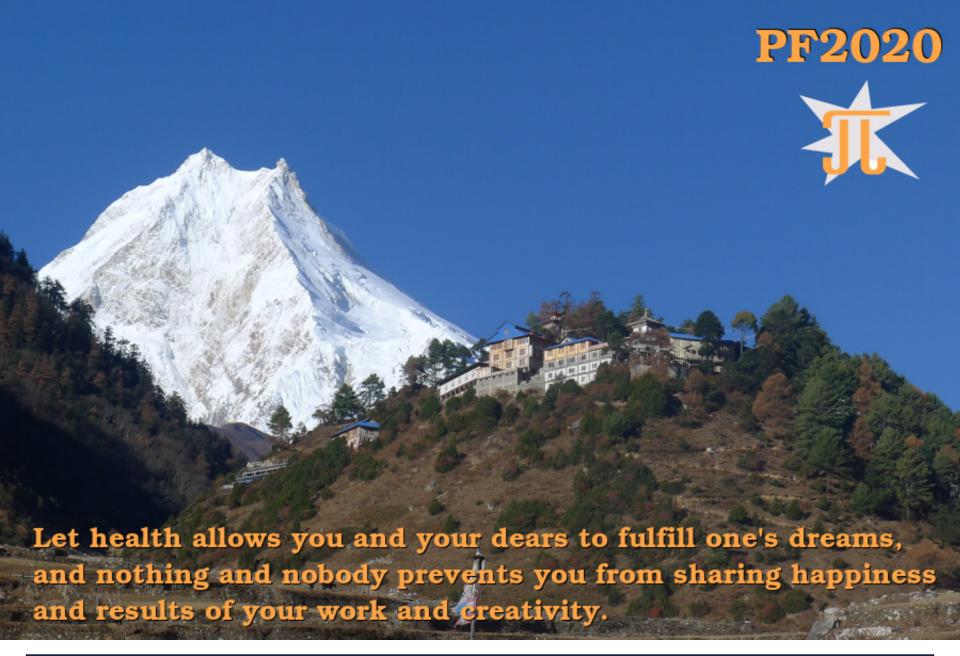

English version partially supported by:

European Social Fund Prague & EU: We invests in your future.

Important Introductory Note

- The goal is to understand the structure of the computer so you can make better use of its options to achieve its higher performance.
- It is also discussed interconnection of HW / SW
- Webpages:

https://cw.fel.cvut.cz/b192/courses/b35apo/ https://dcenet.felk.cvut.cz/apo/ - they will be opened

- Some followup related subjects:
 - B4M35PAP Advanced Computer Architectures
 - B3B38VSY Embedded Systems
 - B4M38AVS Embedded Systems Application
 - B4B35OSY Operating Systems (OI)
 - B0B35LSP Logic Systems and Processors (KyR + part of OI)
- Prerequisite: Šusta, R.: APOLOS, CTU-FEE 2016, 51 pg.

Important Introductory Note

The course is based on a world-renowned book of authors
 Paterson, D., Hennessey, V.: Computer Organization and Design,
 The HW/SW Interface. Elsevier, ISBN: 978-0-12-370606-5

David Andrew Patterson

University of California, Berkeley

Works: RISC processor Berkley RISC → SPARC, DLX, RAID, Clusters, RISC-V

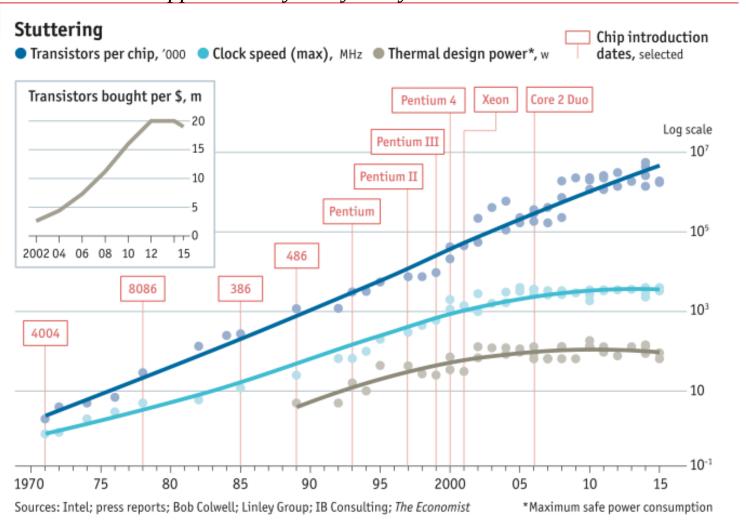

John Leroy Hennessy

10th President of Stanford University Works: RISC processors MIPS, DLX a MMIX

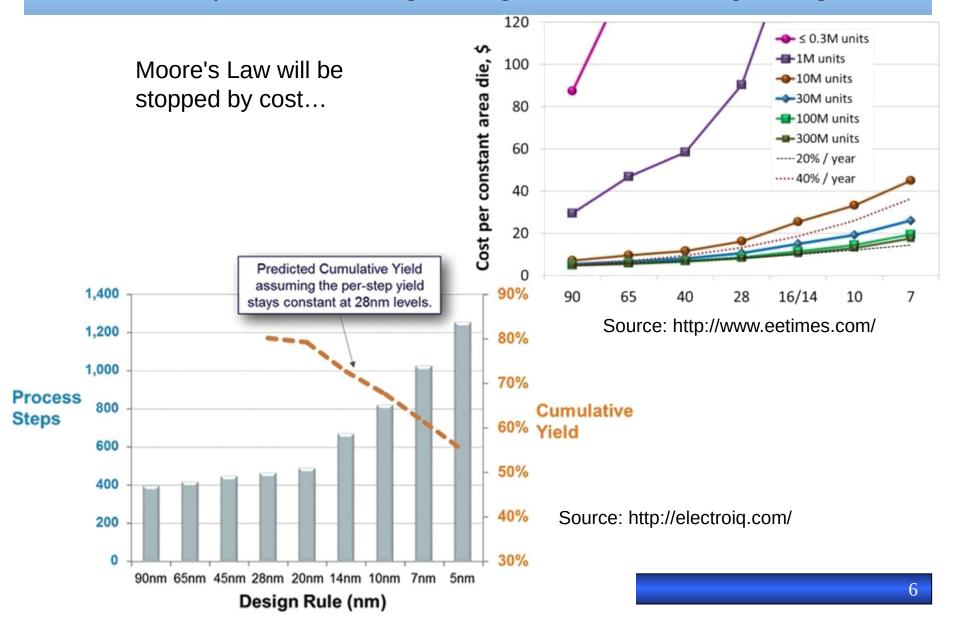

2017 Turing Award for pioneering a systematic, quantitative approach to the design and evaluation of computer architectures with enduring impact on the microprocessor industry. → A New Golden Age for Computer Architecture – RISC-V

Moore's Law

Gordon Moore, founder of Intel, in 1965: " *The number of transistors on integrated circuits doubles approximately every two years*"

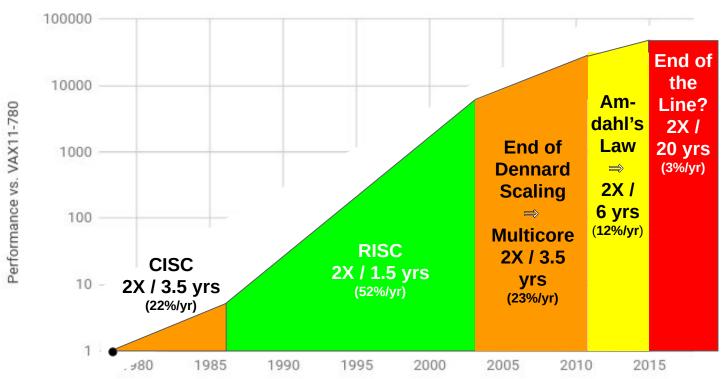

The cost of production is growing with decreasing design rule

End of Growth of Single Program Speed?

40 years of Processor Performance

Based on SPECintCPU. Source: John Hennessy and David Patterson, Computer Architecture: A Quantitative Approach, 6/e. 2018

Processors Architectures Development in a Glimpse

 1960 – IBM incompatible families → IBM System/360 – one ISA to rule them all,

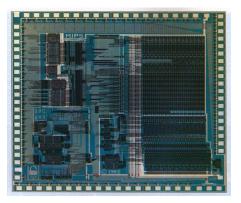

Model	M30	M40	M50	M65
Datapath width	8 bits	16 bits	32 bits	64 bits
Microcode size	4k x 50	4k x 52	2.75k x 85	2.75k x 87
Clock cycle time (ROM)	750 ns	625 ns	500 ns	200 ns
Main memory cycle time	1500 ns	2500 ns	2000 ns	750 ns
Price (1964 \$)	\$192,000	\$216,000	\$460,000	\$1,080,000
Price (2018 \$)	\$1,560,000	\$1,760,000	\$3,720,000	\$8,720,000

- 1976 Writable Control Store, Verification of microprograms, David Patterson Ph.D., UCLA, 1976
- Intel iAPX 432: Most ambitious 1970s micro, started in 1975 32-bit capability-based object-oriented architecture, Severe performance, complexity (multiple chips), and usability problems; announced 1981
- Intel 8086 (1978, 8MHz, 29,000 transistors), "Stopgap" 16-bit processor, 52 weeks to new chip, architecture design 3 weeks (10 person weeks) assembly-compatible with 8 bit 8080, further i80286 16-bit introduced some iAPX 432 lapses, i386 paging

CISC and RISC

- IBM PC 1981 picks Intel 8088 for 8-bit bus (and Motorola 68000 was out of main business)
- Use SRAM for instruction cache of user-visible instructions
- Use simple ISA Instructions as simple as microinstructions, but not as wide, Compiled code only used a few CISC instructions anyways, Enable pipelined implementations
- Chaitin's register allocation scheme benefits load-store ISAs
- Berkeley (RISC I, II → SPARC) & Stanford RISC Chips (MIPS)

Stanford MIPS (1983) contains 25,000 transistors, was fabbed in 3 μ m &4 μ m NMOS, ran at 4 MHz (3 μ m), and size is 50 mm2 (4 μ m) (Microprocessor without Interlocked Pipeline Stages)

CISC and RISC – PC and Post PC Era

- CISC executes fewer instructions per program (≈ 3/4X instructions), but many more clock cycles per instruction (≈ 6X CPI)
 - ⇒ RISC ≈ 4X faster than CISC

PC Era

- Hardware translates x86 instructions into internal RISC Instructions (Compiler vs Interpreter)
- Then use any RISC technique inside MPU
- > 350M / year !
- x86 ISA eventually dominates servers as well as desktops

PostPC Era: Client/Cloud

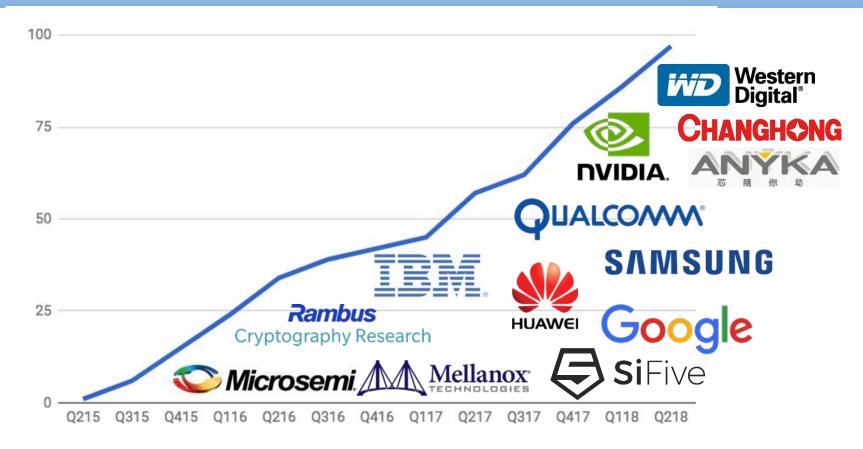

- IP in SoC vs. MPU
- Value die area, energy as much as performance
- > 20B total / year in 2017
- 99% Processors today are RISC
- Marketplace settles debate

- Alternative, Intel Itanium VLIW, 2002 instead 1997
- "The Itanium approach...was supposed to be so terrific –until it turned out that the wished-for compilers were basically impossible to write." - Donald Knuth, Stanford

RISC-V

- ARM, MIPS, SPARC, PowerPC Commercialization and extensions results in too complex CPUs again, with license and patents preventing even original investors to use real/actual implementations in silicon to be used for education and research
- Krste Asanovic and other prof. Patterson's students initiated development of new architecture (start of 2010), initial estimate to design architecture 3 months, but 3 years
- Simple, Clean-slate design (25 years later, so can learn from mistakes of predecessors, Avoids µarchitecture or technology-dependent features), Modular, Supports specialization, Community designed
- A few base integer ISAs (RV32E, RV32I, RV64I)
- Standard extensions (M: Integer multiply/divide, A: Atomic memory operations, F/D: Single/Double-precision Fl-point, C: Compressed Instructions (<x86), V: Vector Extension for DLP (>SIMD**))
- Domain Specific Architectures (DSAs)

RISC-V Foundation Members since 2015

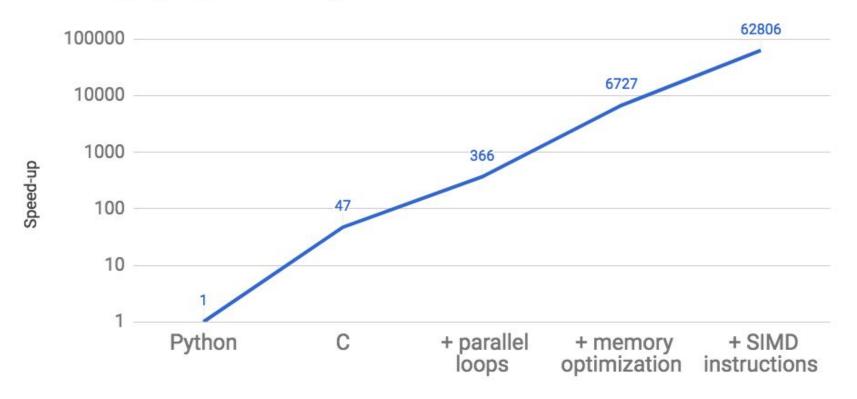

Open Architecture Goal

Create industry-standard open ISAs for all computing devices "Linux for processors"

What's the Opportunity?

Matrix Multiply: relative speedup to a Python version (18 core Intel)

Matrix Multiply Speedup Over Native Python

Source: "There's Plenty of Room at the Top," Leiserson, et. al., to appear.

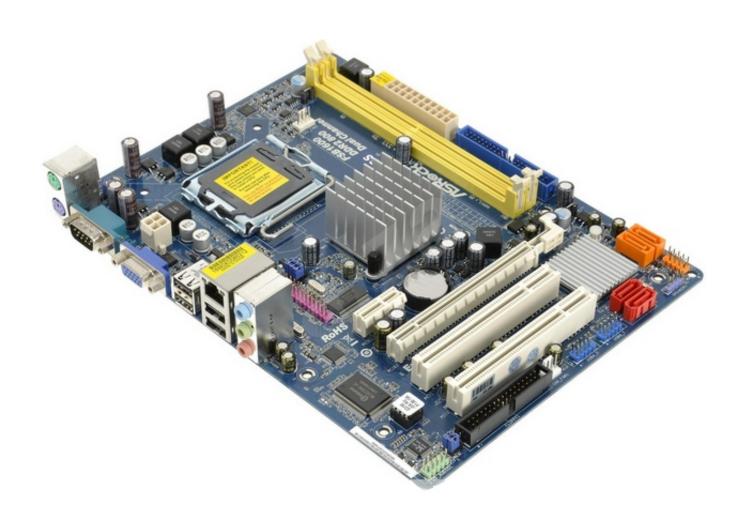

Domain Specific Architectures (DSAs)

- Achieve higher efficiency by tailoring the architecture to characteristics of the domain
- Not one application, but a domain of applications
 - -Different from strict ASIC
- Requires more domain-specific knowledge then general purpose processors need
- Examples: (Neural network processors for machine learning, GPUs for graphics, virtual reality)
- Programmable network switches and interfaces
- More effective parallelism for a specific domain: (SIMD vs. MIMD, VLIW vs. Speculative, out-of-order)
- More effective use of memory bandwidth (User controlled versus caches)
- Eliminate unneeded accuracy (IEEE replaced by lower precision FP, 32-64 bit bit integers to 8-16 bit integers)
- Domain specific programming language

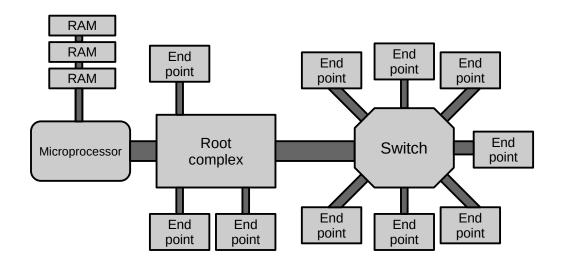

DSL/DSA Summary

- Lots of opportunities
- But, new approach to computer architecture is needed
- The Renaissance computer architecture team is vertically integrated. Understands:
 - Applications
 - DSLs and related compiler technology
 - Principles of architecture
 - Implementation technology
- Everything old is new again!
- Open Architectures
 - Why open source compilers and operating systems but not ISAa?
 - What if there were free and open ISAs we could use for everything?

Display

High speed I/F (HSIC/ USB)

Audio

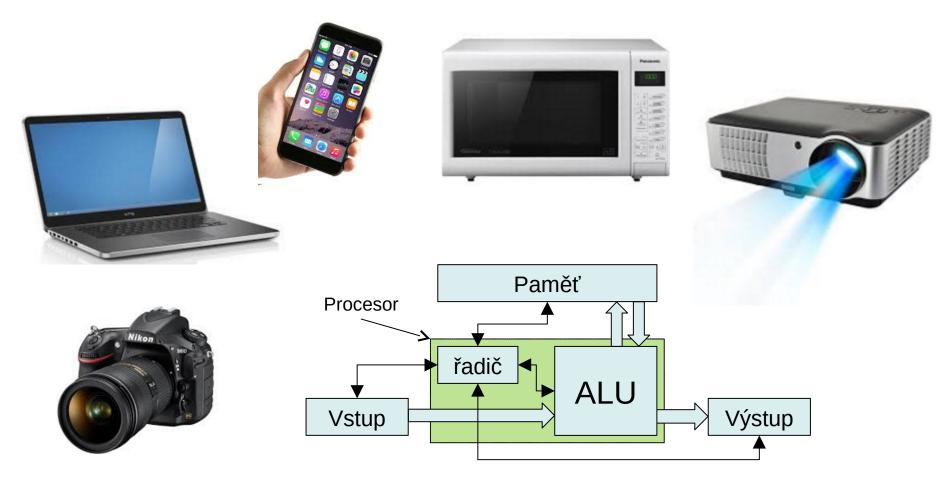

DSP processor for audio

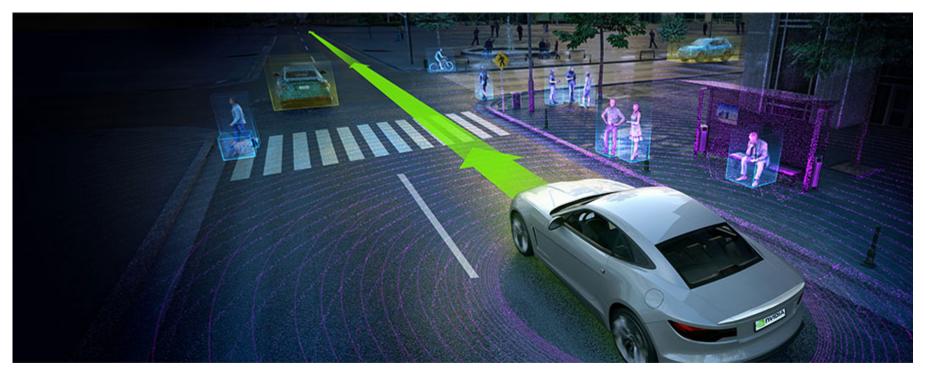

Common concept

• The processor performs stored memory (ROM, RAM) instructions to operate peripherals, to respond to external events and to process data.

Example of Optimization

Autonomous cars

Source: http://www.nvidia.com/object/autonomous-cars.html

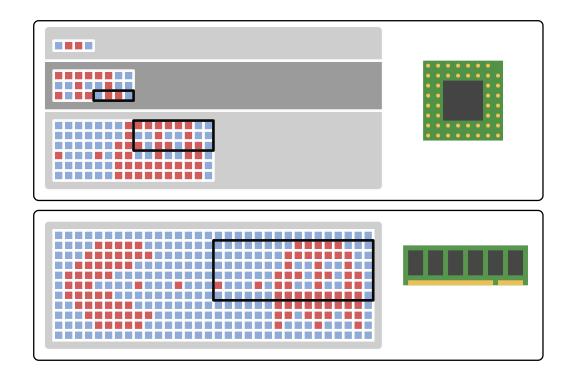

Many artificial intelligence tasks are based on deep neural networks (deep neural networks)

Neural network passage -> matrix multiplication

- How to increase calculation?
- The results of one of many experiments
 - Naive algorithm $(3 \times for) 3.6 s = 0.28 FPS$
 - Optimizing memory access 195 ms = 5.13 FPS (necessary knowledge of HW)
 - 4 cores— 114 ms = 8.77 FPS (selection of a proper synchronization)
 - GPU (256 processors) 25 ms = 40 FPS (knowledge of data transfer between CPU and coprocessors)
- Source: Naive algorithm, library Eigen (1 core), 4 cores (2 physical on i7-2520M, compiler flags -03), GPU results Joela Matějka, Department of Control Engineering, FEE, CTU https://dce.fel.cvut.cz/
- How to speedup?

Optimize Memory Accesses

- Algorithm modification with respect to memory hierarchy
- Data from the (buffer) memory near the processor can be obtained faster (but fast memory is small in size)

Prediction of jumps / accesses to memory

- •In order to increase average performance, the execution of instructions is divided into several phases => the need to read several instructions / data in advance
- Every condition (if, loop) means a possible jump - poor prediction is expensive
- •It is good to have an idea of how the predictions work and what alternatives there are on the CPU / HW. (Eg vector / multimedia inst.)

MZ_APO - Board

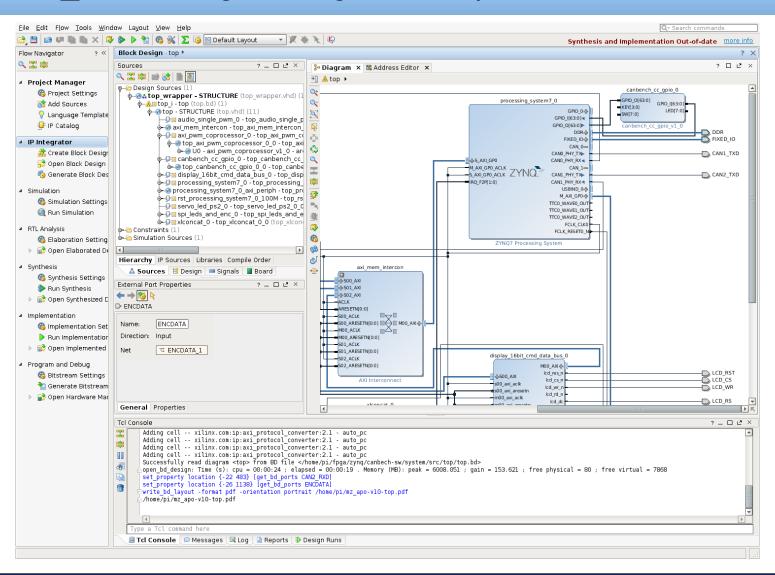

you will later work with this board

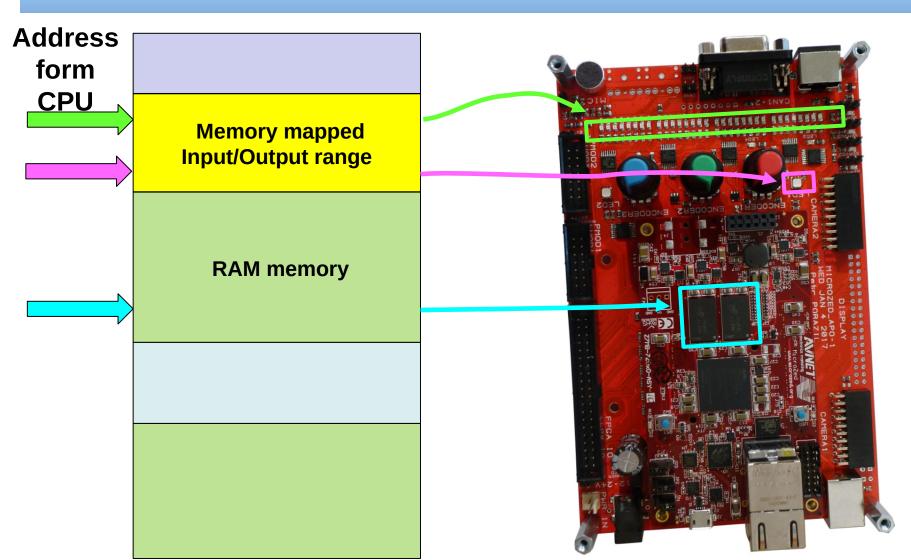

MZ_APO – Features

- The core chip: Zynq-7000 All Programmable SoC
- Typ: Z-7010, device XC7Z010
- CPU: Dual ARM® Cortex™-A9 MPCore™ @ 866 MHz (NEON™ & Single / Double Precision Floating Point)
 2x L1 32+32 kB, L2 512 KB
- FPGA: 28K Logic Cells (~430K ASIC logic gates, 35 kbit)
- Computational capability of FPGA DSP blocks: 100 GMACs
- Memory for FPGA design: 240 KB
- Memory on MicroZed board: 1GB
- Operating system: GNU/Linux
 - GNU LIBC (libc6) 2.28-10
 - Kernel: Linux 4.19.59-rt22-00005-gedf9096397ae
 - Distribution: Debian 10 (Buster)

Back to the Motivational Example of Autonomous Driving

The result of a good knowledge of hardware

- Acceleration (in our case 18 × using the same number of cores)
- Reduce the power required
- Energy saving
- Possibility to reduce current solutions
- Using GPUs, we process 40 fps.

 But in an embedded device, it is sometimes necessary to reduce its consumption and cost. There are used very simple processors or microcontrollers, sometimes without real number operations, and programmed with low-level C language.

Applicability of Knowledge and Techniques from the Course

- Applications not only in autonomous control
- In any embedded device reduce size, consumption, reliability
- In data sciences considerably reduce runtime and energy savings in calculations
- In the user interface improving application response
- Practically everywhere...

Computer – Abstraction Levels

Reference: John Kubiatowicz: EECS 252 Graduate Computer Architecture, Lecture 1. University of California, Berkeley

Reasons to Study Computer Architectures

- To invent/design new computer architectures
- To be able to integrate selected architecture into silicon
- To gain knowledge required to design computer hardware/ systems (big ones or embedded)
- To understand generic questions about computers, architectures and performance of various architectures
- To understand how to use computer hardware efficiently (i.e. how to write good software)
 - It is not possible to efficiently use resources provided by any (especially by modern) hardware without insight into their constraints, resource limits and behavior
 - It is possible to write some well paid applications without real understanding but this requires abundant resources on the hardware level. But no interesting and demanding tasks can be solved without this understanding.

More Motivation and Examples

- The knowledge is necessary for every programmer who wants to work with medium size data sets or solve little more demanding computational tasks
- No multimedia algorithm can be implemented well without this knowledge
- The 1/3 of the course is focussed even on peripheral access
- Examples
 - Facebook HipHop for PHP → C++/GCC → machine code
 - BackBerry (RIM) our consultations for time source
 - RedHat JAVA JIT for ARM for future servers generation
 - Multimedia and CUDA computations
 - Photoshop, GIMP (data/tiles organization in memory)
 - Knot-DNS (RCU, Copy on write, Cuckoo hashing,)

The Course's Background and Literature

- Course is based on worldwide recognized book and courses; evaluation Graduate Record Examination – GRE Paterson, D., Henessy, J.: Computer Organization and Design, The HW/SW Interface. Elsevier, ISBN: 978-0-12-370606-5
 - John L. Henessy president of Stanford University, one of founders of MIPS Computer Systems Inc.
 - David A. Patterson leader of Berkeley RISC project and RAID disks research
- Our experience even includes distributed systems, embedded systems design (of mobile phone like complexity), peripherals design, cooperation with carmakers, medical and robotics systems design

Topics of the Lectures

- Architecture, structure and organization of computers and its subsystems.
- Floating point representation
- Central Processing Unit (CPU)
- Memory
- Pipelined instruction execution
- Input/output subsystem of the computer
- Input/output subsystem (part 2)
- External events processing and protection
- Processors and computers networks
- Parameter passing
- Classic register memory-oriented CISC architecture
- INTEL x86 processor family
- CPU concepts development (RISC/CISC) and examples
- Multi-level computer organization, virtual machines

Topics of Seminaries

- 1 Introduction to the lab
- 2 Data representation in memory and floating point
- 3 Processor instruction set and algorithm rewriting
- 4 Hierarchical concept of memories, cache part 1
- 5 Hierarchical concept of memories, cache part 2
- 6 Pipeline and gambling
- 7 Jump prediction, code optimization
- 8 I / O space mapped to memory and PCI bus
- 9 HW access from C language on MZ_APO
- Semestral work

Classification and Conditions to Pass the Subject

Conditions for assessment:

Category	Points	Required minimum	Remark
4 homeworks	36	12	3 of 4
Activity	8	0	
Team project	24	5	
Sum	60 (68)	30	

Exam:

Category	Points	Required minimum
Written exam part	30	15
Oral exam part	+/- 10	0

Grade	Points range
Α	90 and more
В	80 - 89
С	70 - 79
D	60 - 69
E	50 - 59
F	less than 50

The First Lecture Contents

- Number representation in computers
 - numeral systems
 - integer numbers, unsigned and signed
 - boolean values
- Basic arithmetic operations and their implementation
 - addition, subtraction
 - shift right/left
 - multiplication and division

Motivation: What is the output of next code snippet?

```
int main() {
  int a = -200;
  printf("value: %u = %d = %f = %c \n", a, a,
  *((float*)(&a)), a);
  return 0;
value: 4294967096 = -200 = nan = 8
and memory content is: 0x38 0xff 0xff 0xff
when run on little endian 32 bit CPU.
```

Non-positional numbers ©

http://diameter.si/sciquest/E1.htm

The value is the sum: 1 333 331

Terminology Basics

- Positional (place-value) notation
- Decimal/radix point
- z ... base of numeral system

- Module = \mathbb{Z} , one increment/unit higher than biggest representable number for given encoding/notation
- A, the representable number for given n and m selection, where k is natural number in range (0,zn+m+1-1)

$$0 \le A = k \cdot \varepsilon < \mathcal{Z}$$

The representation and value

$$A \sim a_n a_{n-1} \dots a_0, a_1 \dots a_{-m}$$

$$A = a_n z^n + a_{n-1} z^{n-1} + \dots + a_0 + a_1 z^{-1} \dots a_{-m} z^{-m}$$

-m

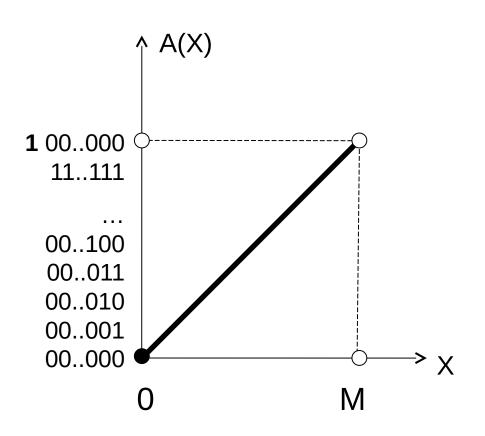

Unsigned Integers

Language C: unsigned int

Integer Number Representation (unsigned, non-negative)

- The most common numeral system base in computers is z=2
- The value of **a**_i is in range {0,1,...z-1}, i.e. {0,1} for base 2
- This maps to true/false and unit of information (bit)
- We can represent number $0 \dots 2^{n}-1$ when n bits are used
- Which range can be represented by one byte? 1B (byte) ... 8 bits, $2^8 = 256_d$ combinations, values 0 ... $255_d = 0b11111111_h$
- Use of multiple consecutive bytes
 - 2B ... 2¹⁶ = 65536_d, 0 ... 65535_d = 0xFFFF_h ,(h ... hexadecimal, base 16, a in range 0, ... 9, A, B, C, D, E, F)
 - 4B ... $2^{32} = 4294967296_d$, 0 ... $4294967295_d = 0$ xFFFFFFF_h

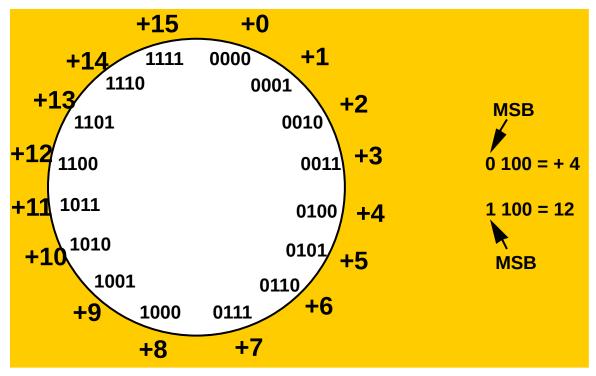

Unsigned Integer

binary value	unsigned int
0000000	0 ₍₁₀₎
00000001	1 ₍₁₀₎
:	i i
01111101	125 ₍₁₀₎
01111110	126 ₍₁₀₎
01111111	127 ₍₁₀₎
10000000	128 ₍₁₀₎
10000001	129(10)
10000010	130(10)
:	i i
11111101	253 ₍₁₀₎
11111110	254 ₍₁₀₎
11111111	255 ₍₁₀₎

Unsigned 4-bit numbers

Assumptions:we'll assume a 4 bit machine word

Cumbersome subtraction

[Seungryoul Maeng:Digital Systems]

Signed Numbers

Language C: int signed int

B35APO Computer Architectures

Signed Integer Numbers

- Work with negative numbers is required for many applications
- When appropriate representation is used then same hardware (with minor extension) can be used for many operations with signed and unsigned numbers
- Possible representations
 - sign-magnitude code, direct representation, sign bit
 - two's complement
 - ones' complement
 - excess-K, offset binary or biased representation

Two's Complement (Complement to Module)

- The most frequent code
- The unsigned sum of two opposite numbers representations with the same absolute value is 00000000H!
- Transform to the representation

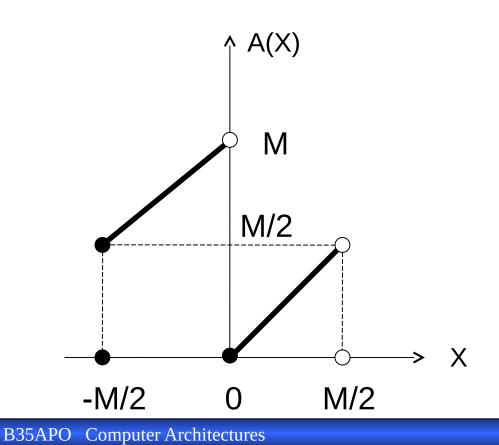

$$D(A) = A$$
 iff $A \ge 0$
 $D(A) = Z - |A|$ iff $A < 0$

- The name is misleading, it is module (Z) complement actually
- Negative value can be encoded as digit by digit z-1-a_i and then add 1
- For z=2, bit by bit complement $(0\rightarrow 1, 1\rightarrow 0)$ and addition of 1

Decimal value	4 bit two's compliment
6	0110
-6	1010

Two's Complement

For **N** bits used for representation is represented value range:

Binární hodnota	Dvojkový doplněk
0 0000000	0 ₍₁₀₎
0 0000001	1 ₍₁₀₎
:	:
0 1111101	125 ₍₁₀₎
0 1111110	126 ₍₁₀₎
0 1111111	127 ₍₁₀₎
10000000	-128 ₍₁₀₎
1 0000001	-127 ₍₁₀₎
1 0000010	-126 ₍₁₀₎
:	:
1 1111101	-3 ₍₁₀₎
1 1111110	-2 ₍₁₀₎
1 1111111	-1 ₍₁₀₎

Two's Complement - Examples

Advantages

Continuous range when cyclic arithmetic is considered Single and one to one mapping of value 0 Same HW for signed and unsigned adder

Disadvantages

Asymmetric range (-(-1/2Z))

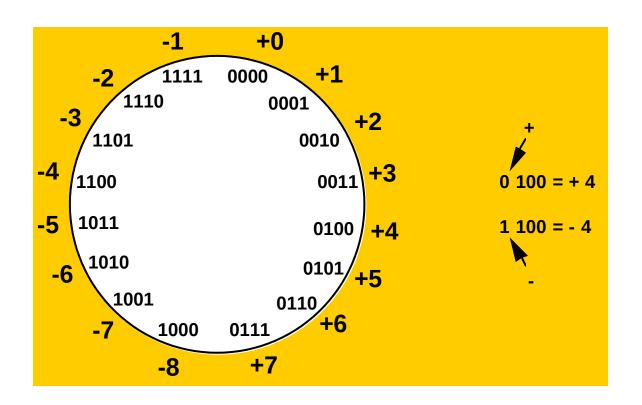

Examples:

```
• 0D = 00000000H,
```

•
$$1_D = 00000001_H$$
, $-1_D = FFFFFFF_H$,

•
$$3D = 00000003H$$
, $-3D = FFFFFFDH$,

Twos Complement (In Czech: Druhý doplněk)

Only one representation for 0

One more negative number than positive number

[Seungryoul Maeng:Digital Systems]

Two's Complement and the C Language

- Two's complement is most used signed integer numbers representation in computers
- Complement arithmetic is often used as its synonym
- "C" programing language speaks about integer numeric type without sign as unsigned integers and they are declared in source code as unsigned int.
- The numeric type with sign is simply called *integers* and is declared as signed int.
- Considerations about overflow and underflow are described later.

Two's Complement – Addition and Subtraction

Addition

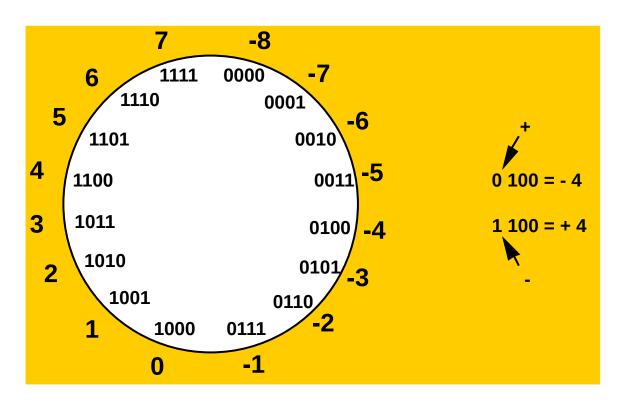

- $0000000 \ 0000 \ 0111_{B} \approx 7_{D}$ Symbols use: $0=0_{H}, \ 0=0_{B}$
- + $0000000 0000 0110_{\rm B} \approx 6_{\rm D}$
- $0000000 0000 1101_{B} \approx 13_{D}$
- Subtraction can be realized as addition of negated number
 - $0000000 0000 0111_{B} \approx 7_{D}$
 - <u>+ FFFFFF 1111 1010_B ≈ -6_D</u>
 - $0000000 0000 0001_{B} \approx 1_{D}$
- Question for revision: how to obtain negated number in two's complement binary arithmetics?

Other Possibilities

Integer - Biased Representation

- Known as excess-K or offset binary as well
- Transform to the representation $_{-K \dots 0 \dots 2^{n}-1-K}$ D(A) = A+K
- Usually K=Z/2
- Advantages
 - Preserves order of original set in mapped set/representation
- Disadvantages
 - Needs adjustment by -K after addition and +K after subtraction processed by unsigned arithmetic unit
 - Requires full transformation before and after multiplication

Excess-K, Offset Binary or Biased Representation

One 0 representation, we can select count of negative numbers - used e.g. for exponents of real numbers..

Integer arithmetic unit are not designed to calculate with Excess-K numbers [Seungryoul Maeng:Digital Systems]

Addition and Subtraction for the Biased Representation

Short note about other signed number representation

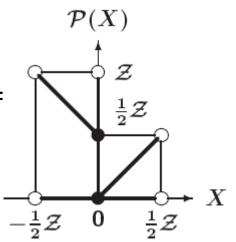

$$\mathcal{A}(A+B) = \mathcal{A}(A) + \mathcal{A}(B) - K$$

$$\mathcal{A}(A-B) = \mathcal{A}(A) - \mathcal{A}(B) + K$$

- Overflow detection
 - for addition:
 same sign of addends and different result sign
 - for subtraction:
 signs of minuend and subtrahend are opposite and sign of the result is opposite to the sign of minuend

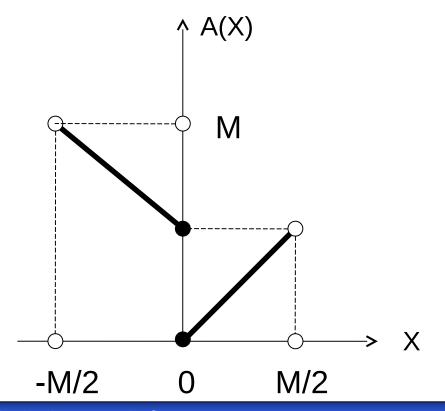

Integer – Sign-Magnitude Code

- Sign and magnitude of the value (absolute value)
- Natural to humans -1234, 1234
- One (usually most significant MSB) bit of the memory location is used to represent the sign
- Bit has to be mapped to meaning
- Common use 0 ≈ "+", 1 ≈ "-"
- Disadvantages:
 - When location is k bits long then only k-1 bits hold magnitude and each operation has to separate sign and magnitude
 - Two representations of the value 0

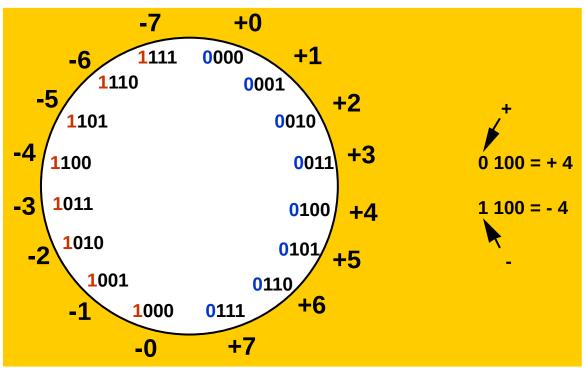

$$-2^{n-1}+1 \dots 0 \dots 2^{n-1}-1$$

Sign and Magnitude Representation

Binary value	Code
0 0000000	+0 ₍₁₀₎
0 0000001	1 ₍₁₀₎
:	:
0 1111101	125 ₍₁₀₎
0 1111110	126 ₍₁₀₎
0 1111111	127 ₍₁₀₎
1 0000000	-O ₍₁₀₎
1 0000001	-1 ₍₁₀₎
1 0000010	-2 ₍₁₀₎

1 1111101	-125 ₍₁₀₎
1 1111110	-126 ₍₁₀₎
1 1111111	-127 ₍₁₀₎

Sign and Magnitude Representation

- Cumbersome addition/subtraction
- Sign+Magnitude usually used only for float point numbers

[Seungryoul Maeng:Digital Systems]

Integers – Ones' Complement

Transform to the representation

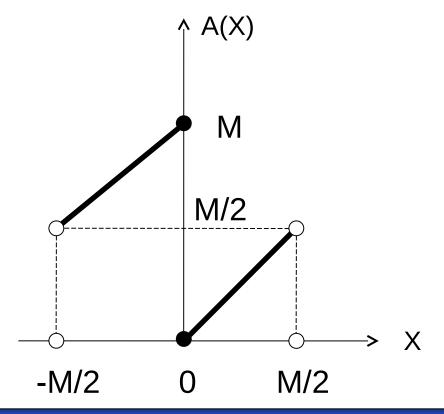

$$-2^{n-1}+1 \dots 0 \dots 2^{n-1}-1$$

$$D(A) = A$$
 iff $A \ge 0$

$$D(A) = Z-1-|A|$$
 iff A<0 (i.e. subtract from all ones)

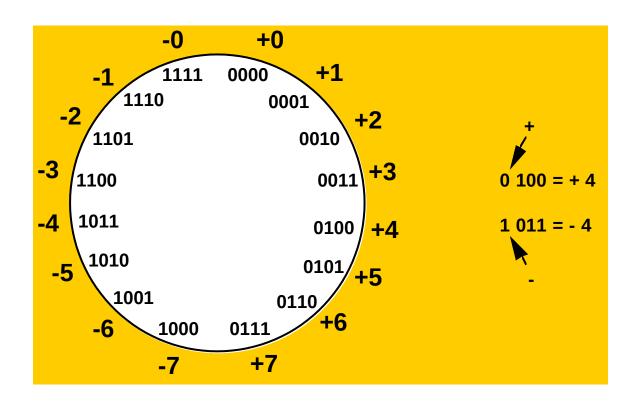

- Advantages
 - Symmetric range
 - Almost continuous, requires hot one addition when sign changes
- Disadvantage
 - Two representations of value 0
 - More complex hardware
- Negate (-A) value can be computed by bitwise complement (flipping) of each bit in representation

Ones Complement

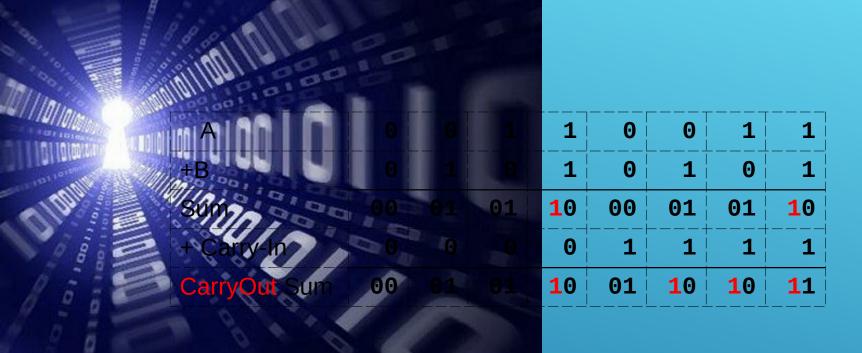

Binary value	Code
0 0000000	0 ₍₁₀₎
0 0000001	1 ₍₁₀₎
:	:
0 1111101	125 ₍₁₀₎
0 1111110	126 ₍₁₀₎
0 1111111	127 ₍₁₀₎
1 0000000	-127 ₍₁₀₎
1 0000001	-126 ₍₁₀₎
1 0000010	-125 ₍₁₀₎
:	:
1 1111101	-2 ₍₁₀₎
1 1111110	-1 ₍₁₀₎
1 1111111	-O ₍₁₀₎

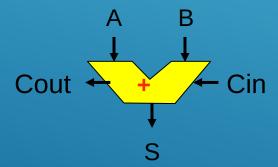

Ones Complement (In Czech: První doplněk)

Still two representations of 0! This causes some problems Some complexities in addition, nowadays nearly not used

[Seungryoul Maeng:Digital Systems]

OPERATION WITH INTEGERS

Direct Realization of Adder as Logical Function

	Number of logic operations
bit width	for calculating sum
1	3
2	22
3	89
4	272
5	727
6	1567
7	3287
8	7127
9	17623
10	53465
11	115933

Complexity is higher than O(2ⁿ)

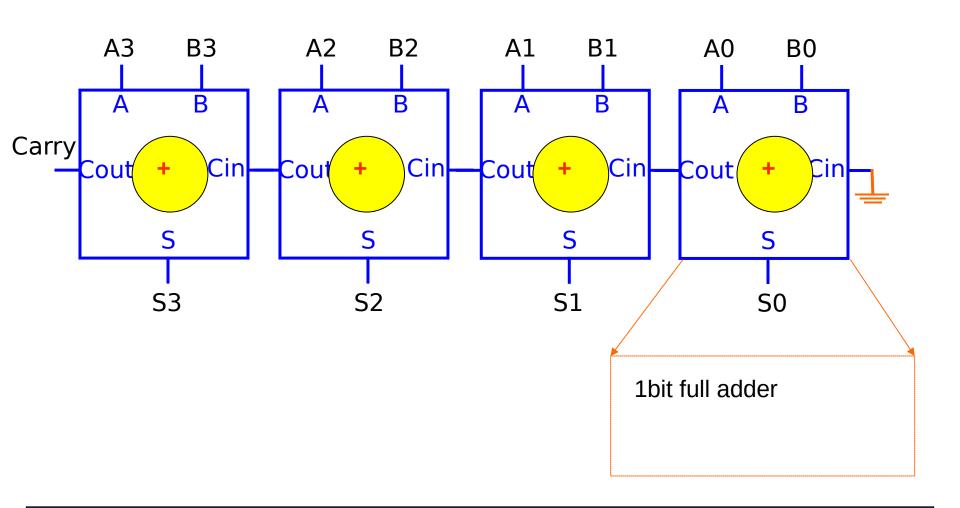

The calculation was performed by BOOM logic minimizer created at the Department of Computer Science CTU-FEE

1bit Full Adder

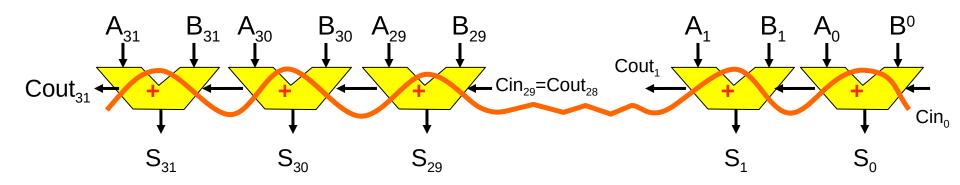

Α	0	0	1	1	0	0	1	1
+B	0	1	0	1	0	1	0	1
Sum	00	01	01	1 0	99	01	01	10
+ Carry-In	0	0	0	0	1	1	1	1
CarryOut Sum	00	01	01	10	01	10	10	11

Simple Adder

Simple Adder

Simplest N-bit adder

we chain 1-bit full adders

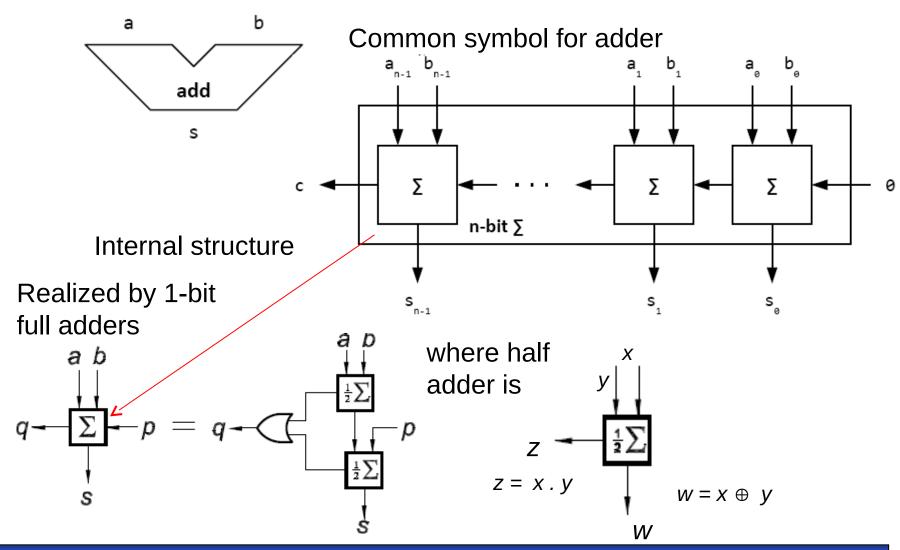

"Carry" ripple through their chain

Minimal number of logical elements

Delay is given by the last Cout - 2*(N-1)+ 3 gates of the last adder

= (2 N+1) times propagation delay of 1 gate

Hardware of Ripple-Carry Adder

Fast Parallel Adder Realization and Limits

- The previous, cascade based adder is slow carry propagation delay
- The parallel adder is combinatorial circuit, it can be realized through sum of minterms (product of sums), two levels of gates (wide number of inputs required)
- But for 64-bit adder 10²⁰ gates is required

Solution #1

 Use of carry-lookahead circuits in adder combined with adders without carry bit

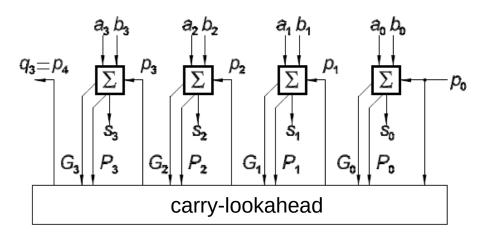

Solution #2

Cascade of adders with fraction of the required width
 Combination (hierarchy) of #1 and #2 can be used for wider inputs

Speed of the Adder

- Parallel adder is combinational logic/circuit. Is there any reason to speak about its speed? Try to describe!
- Yes, and it is really slow. Why?
- Possible enhancement adder with carry-lookahead (CLA) logic!

CLA - Carry-lookahead

- Adder combined with CLA provides enough speedup when compared with parallel ripple-carry adder and yet number of additional gates is acceptable
- CLA for 64-bit adder increases hardware price for about 50% but the speed is increased (signal propagation time decreased) 9 times.
- The result is significant speed/price ratio enhancement.

The Basic Equations for the CLA Logic

- Let:
 - the generation of carry on position (bit) j is defined as:

$$g_j = x_j y_j$$

the need for carry propagation from previous bit:

$$p_j = x_j \oplus y_j = x_j \overline{y}_j \ \overline{x}_j y_j$$

- Then:
 - the result of sum for bit j is given by:

$$s_j = c_j (\overline{x_j \oplus y_j})^{\vee} \overline{c}_j (x_j \oplus y_j) = c_j \overline{p}_j \overline{c}_j (x_j \oplus y_j) = c_j \overline{p}_j \overline{c}_j (x_j \oplus y_j)$$

• and carry to the higher order bit (j+1) is given by:

$$c_{j+1} = x_j y_j \lor (x_j \oplus y_j) c_j = g_j \lor p_j c_j$$

CLA

The carry can be computed as:

$$c_{1} = g_{0} \lor p_{0}c_{0}$$

$$c_{2} = g_{1} \lor p_{1}c_{1} = g_{1} \lor p_{1}(g_{0} \lor p_{0}c_{0}) = g_{1} \lor p_{1}g_{0} \lor p_{1}p_{0}c_{0}$$

$$c_{3} = g_{2} \lor p_{2}c_{2} = g_{2} \lor p_{2}(g_{1} \lor p_{1}g_{0} \lor p_{1}p_{0}c_{0}) = g_{2} \lor p_{2}g_{1} \lor p_{2}p_{1}g_{0} \lor p_{2}p_{1}p_{0}c_{0}$$

$$c_{4} = g_{3} \lor p_{3}c_{3} = \dots = g_{3} \lor p_{3}g_{2} \lor p_{3}p_{2}g_{1} \lor p_{3}p_{2}p_{1}g_{0} \lor p_{3}p_{2}p_{1}p_{0}c_{0}$$

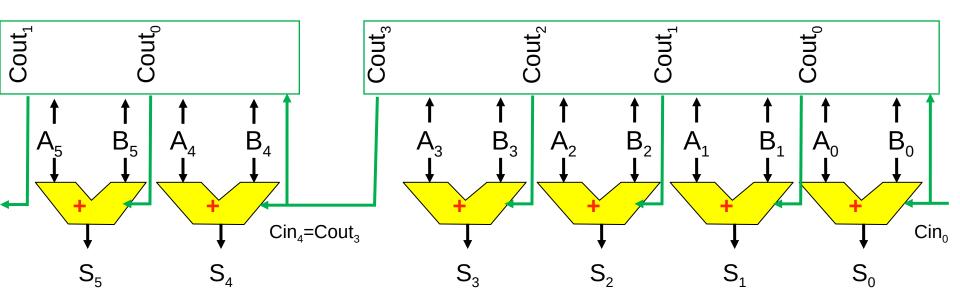

$$c_{5} = \dots$$

Description of the equation for c_3 as an example:

The carry input for bit 3 is active **when** carry is generated in bit 2 **or** carry propagates condition holds for bit 2 and carry is generated in the bit 1 **or** both bits 2 and 1 propagate carry and carry is generated in bit 0

32bit CLA "carry look-ahead" adder

The carry-lookahead adder calculates one or more carry bits before the sum, which reduces the wait time to calculate the result of the larger value bits

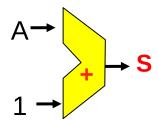

Static "carry look ahead (CLA)" unit for 4 bits

Dec. **Binary Binary** +1 -1 Increment / Decrement Very fast operations that do not need an adder! The last bit is always negated, and the previous ones are negated according to the end 1 / 0

Special Case +1/-1

S1=A1 xor A0

S2=A2 xor (A1 and A0)

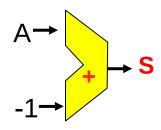

Eq:
$$S_i = A_i$$
 xor $(A_{i-1}$ and A_{i-2} and ... A_1 and A_0); $i=0..n-1$

S0=not A0

S1=A1 xor (not A0)

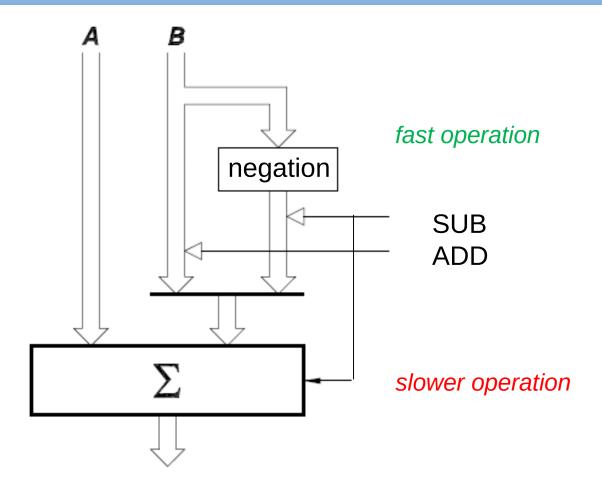

S2=A2 xor (not A1 and not A0)

Eq:
$$S_i = A_i$$
 xor (not A_{i-1} and ... and not A_0); i=0..n-1

The number of circuits is given by the arithmetic series, with the complexity $O(n^2)$ where n is the number of bits. The operation can be performed in parallel for all bits, and for the both +1/-1 operations, we use a circuit that differs only by negations.

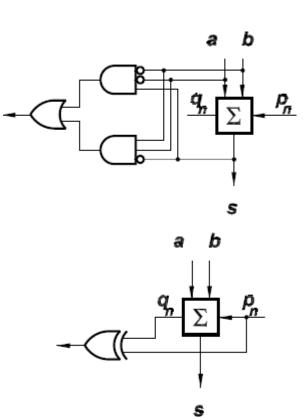

Addition / Subtraction HW

Source: X36JPO, A. Pluháček

Arithmetic Overflow (Underflow)

- Result of the arithmetic operation is incorrect because, it does not fit into selected number of the representation bits (width)
- But for the signed arithmetic, it is not equivalent to the carry from the most significant bit.
- The arithmetic overflow is signaled if result sign is different from operand signs if both operands have same sign
- or can be detected with exclusive-OR of carry to and from the most significant bit

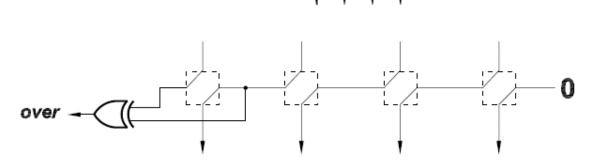

Arithmetic Shift to the Left and to the Right

 arithmetic shift by one to the left/right is equivalent to signed multiply/divide by 2 (digits movement in positional (place-value) representation)

Notice difference between arithmetic, logic and cyclic shift

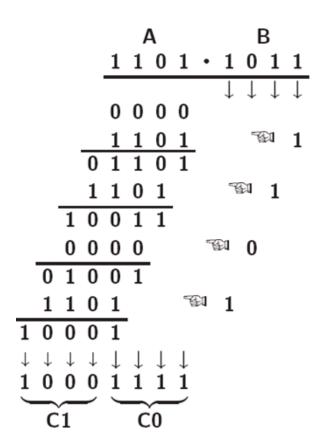

operations

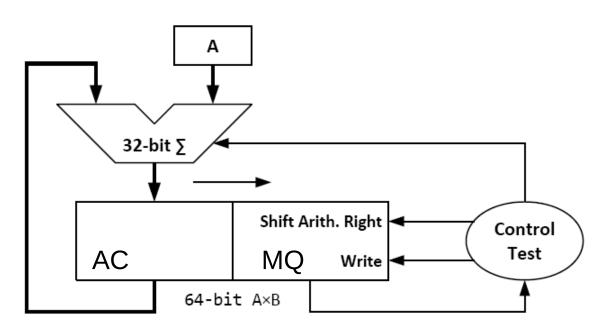

Remark: Barrel shifter can be used for fast variable shifts

Unsigned Binary Numbers Multiplication

Sequential Hardware Multiplier (32b Case)

The speed of the multiplier is horrible

Algorithm for Multiplication

```
A = multiplicand;
MQ = multiplier;
AC = 0;
for(int i=1; i \leq n; i++) // n - represents number of bits
if(MQ<sub>0</sub> = = 1) AC = AC + A; // MQ<sub>0</sub> = LSB of MQ
SR (shift AC MQ by one bit right and insert information about
carry from the MSB from previous step)
end.
```

when loop ends AC MQ holds 64-bit result

Example of the Multiply X by Y

Multiplicand x=110 and multiplier y=101. $x \rightarrow A$, $y \rightarrow MQ$

i	operation	C AC MQ	A	comment
		0 000 101	110	initial setup
1	AC = AC + A	0 110 101		start of the cycle
	SR	0 011 010		
2	nothing	0 011 010		because of $MQ_0 = 0$
	SR	0 001 101		
3	AC = AC + A	0 111 101		
	SR	0 011 110		end of the cycle

The whole operation: $x \times y = 110 \times 101 = 011110$, ($6 \times 5 = 30$) Carry,AC can be mapped to AC,MQ.MSB and A masked by MQ.LSB, then if, add and shift steps are combined to the one.

Signed Multiplication by Unsigned HW for two's Complement

One possible solution (for illustration only)

$$C = A \cdot B$$

Let A and B representations are n bits and result is 2n bits

$$D(C) = D(A) \cdot D(B)$$

- $(D(B) << n)$ if $A < 0$
- $(D(A) << n)$ if $B < 0$

Consider for negative numbers

$$(2^n+A) \cdot (2^n+B) = 2^{2n}+2^nA + 2^nB + A \cdot B$$

where 2²ⁿ is out of the result representation, next two elements have to be eliminated if input is negative

Today more often used separate sign evaluation and multiplication of absolute values.

Wallace Tree Based Multiplier – Required Function

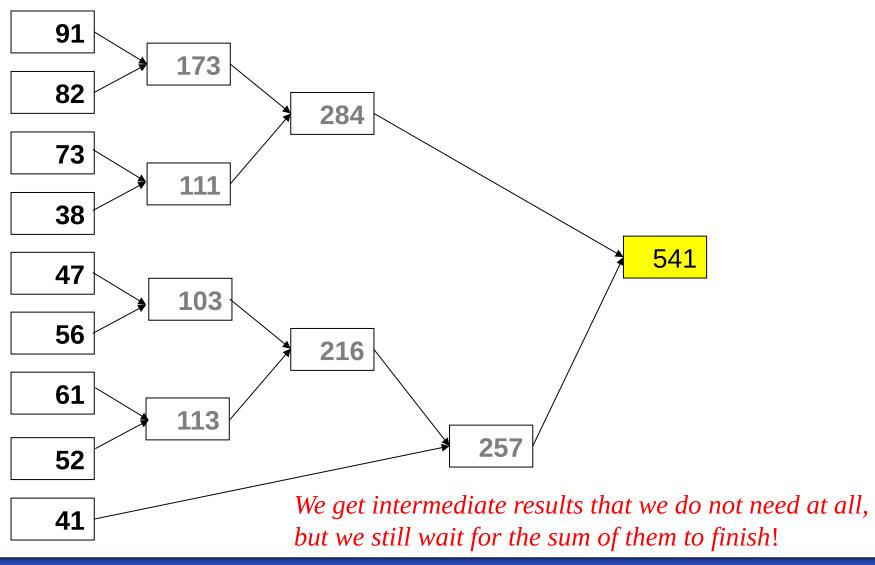

Q=X .Y, X and Y are considered as and 8bit unsigned numbers $(x_7 x_6 x_5 x_4 x_3 x_2 x_1 x_0)$. $(y_7 y_6 y_5 y_4 y_3 y_2 y_1 y_0) =$
