Problem solving by search II

Tomáš Svoboda and Matěj Hoffmann

Vision for Robots and Autonomous Systems, Center for Machine Perception Department of Cybernetics Faculty of Electrical Engineering, Czech Technical University in Prague

April 20, 2021

Notes -

Outline

- Graph search
- Heuristics (how to search faster)
- Greedy
- ► A*. A-star search.

Notes -

A Maze, what could possibly go wrong?

https://youtu.be/WKSoedfRZQ4

Notes -

Analyze the demo run (BFS). What happened? Why did it take that long? Because it is TREE_SEARCH...

Many loops are created and all nodes with depth < 7 need to be expanded first. Goal is at depth 8. Notes for teacher:

```
Working note for demo:
```

```
python3 easy_search_agents.py
```

```
'n' for next
```

```
's' for skip
```

```
code settings:
```

```
MAP = 'maps/easy/easy2.bmp'
```

```
TREE\_SEARCH = True
```

```
node_type = 'BFS'
```

How to decode printout on command line:

- Every iteration ends with: print('End of while loop: length of the frontier:',len(frontier), 'length of the expanded:', len(expanded_states), frontier, frontier.is_empty())
- But note that the algo is written in a general way (like UCS), stopping after expanding the goal node that is why you see also depth 9 in the frontier notes at the end.
- Size of the visualiation can be altered in ./kuimaze/maze.py, look for MAX_CELL_SIZE

Tree search the maze

function TREE_SEARCH(env) return a solution or failure		0	1	2	3	4	
initialize the frontier while frontier do	0	0.00	0.00	0.00	0.00	0.00	0
node = frontier.pop() if goal in node then	1	0.00	0.00	0.00	0.00	0.00	1
break end if	2	0.00	0.00	0.00	0.00	0.00	2
nodes = env.expand(node.state) Add nodes to frontier	3	0.00	0.00	0.00	0.00	0.00	3
end while end function	-						
	4	0.00	0.00	0.00	0.00	0.00	4
		0	1	2	3	4	

Notes -

Make a frontier and expand columns on a paper and follow the algorithm by putting and removing (scratching out) nodes from the list.

4 / 25

Note that there are many more nodes than states (search tree vs. state space).

Tree search seems hugely ineffective. Note that this is (also) because of the state space. It's a maze with undirected egdes. If we had directed edges, there would be much much fewer cycles.

function GRAPH_SEARCH(env) return a solution or failure
 init frontier by the start state

initialize the explored set to be empty
while frontier do
node = frontier.pop()
add node.state to explored
if goal in node then break
end if
nodes = env.expand(node.state)
for all nodes do
 if node.state not in explored (or in frontier) then
 add nodes to frontier
 end if
end for
end while
d function

Do not forget: node is not the same as state!

5 / 25

- Notes -

Think about what is node and what state. What is main difference? How are they connected? Where do they appear? What is node/state in the maze problem?

The main idea: Do not expand a state twice.

function GRAPH_SEARCH(env) return a solution or failure
init frontier by the start state
initialize the explored set to be empty
while frontier do
 node = frontier.pop()
 add node.state to explored
 if goal in node then break
 end if
 nodes = env.expand(node.state)
 for all nodes do
 if node state not in explored (or in frontier) then
 add nodes to frontier
 end if
 end for
 end

- Notes -

Think about what is node and what state. What is main difference? How are they connected? Where do they appear? What is node/state in the maze problem?

The main idea: Do not expand a state twice.

function GRAPH_SEARCH(env) return a solution or failure
init frontier by the start state
initialize the explored set to be empty
while frontier do
 node = frontier.pop()
 add node.state to explored
 if goal in node then break
 end if
 nodes = env.expand(node.state)
 for all nodes to frontier
 end if
 end for
 end for

- Notes –

Few examples of search strategies so far

Run the demos.

Notes -

What is wrong with UCS and other strategies?

Run the demo, or see https://youtu.be/TT5MY8xCgAg

Selecting next node to expand/visit:

$$node \leftarrow \operatorname*{argmin}_{n \in \texttt{frontier}} f(n)$$

What is f(n) for DFS, BFS, and UCS?

The good: (one) frontier as a priority queue

(I.e., priority queue will work universally. Still, stack (LIFO) and queue (FIFO) are (conceptually) the perfect data structures for DFS and BFS, respectively.) The bad: All the *f*(*n*) correspond to the cost from *n* to the start - only backward cost; cost-to-come (to *n*).

Notes -

- DFS: f(n) = -n.depth
- BFS: f(n) = n.depth
- UCS: $f(n) = n.path_cost$

Do humans look back when planing path? Is looking back important at all? If yes, when?

How far are we from the goal **cost-to-go** ? – Heuristics

- A function that estimates how close a state is to the goal.
- Designed for a particular problem.
- We will use h(n) heuristic value of node n.

Notes -

What happens if h(n) = true cost?

Example of heuristics

Straight-line distance to Bucharest.

Illustration of *greedy* failing: Imagine going from Iasi to Fagaras. Neamt will be chosen for expansion. This will add Iasi back. Iasi is closer to Fagaras than Vaslui is and will be expanded again. Infinite loop... (3.5.1. in [2])

Greedy, take the node argmin h(n)

What is wrong (and nice) with the Greedy?

¹Graph example: Ted Grenager

Notes -

Also called "Greedy best-first search" [2]. What will happen in this example:

- 1. Expand "S". Add "a" to frontier.
- 2. Expand "a". Add "b", "d", "e".
- 3. Expand "e" (h = 1). We already have "d".
- 4. Expand "d". Get "G".

Wrong:

- not optimal
- not complete (tree search version) (Can be shown on the Romania example go back.)
- (graph search version is complete only in finite state spaces)

Nice: it is simple.

Greedy, take the node argmin h(n)

What is wrong (and nice) with the Greedy?

A* combines UCS and Greedy

UCS orders by backward (path) cost g(n)Greedy uses heuristics (goal proximity) h(n)

Notes -

A* combines UCS and Greedy

UCS orders by backward (path) cost g(n)Greedy uses heuristics (goal proximity) h(n)

A^{*} orders nodes by: f(n) = g(n) + h(n)

Notes

²Graph example: Dan Klein and Pieter Abbeel

Notes

- f(S) = g(S) + h(S) = 0 + 3 = 3

- expanding/poping this one and crossing out (removing from frontier)

2. $S \rightarrow A$

1. S

$$- f(A) = g(A) + h(A) = 2 + 2 = 4$$

3.
$$S \rightarrow B$$

- f(B) = g(B) + h(B) = 2 + 1 = 3

- expanding this one and crossing out

4.
$$S \rightarrow B \rightarrow G$$

- f(G) = g(G) + h(G) = 5 + 0 = 5

- Should I stop now? No. Pop $S \rightarrow A$ with f = 4.

5.
$$S \rightarrow A \rightarrow G$$

$$- f(G) = g(G) + h(G) = 4 + 0 = 4$$

- This is now cheapest on the frontier. I pop/expand and I'm done.

Note: h is a function of the state. g is a function of a node (the path matters).

Is A* optimal?

What is the problem?

³Graph example: Dan Klein and Pieter Abbeel

Notes -

Try to answer the question before going to the next slide.

1. S

$$- f(S) = g(S) + h(S) = 0 + 7 = 7$$

- expanding/poping this one and crossing out (removing from frontier)

2. $S \rightarrow A$

$$- f(A) = g(A) + h(A) = 1 + 6 = 7$$

- 3. $S \rightarrow G$
 - f(G) = g(G) + h(G) = 5 + 0 = 5
 - This is now cheapest on the frontier. I pop/expand and I'm done.

Ooops! That's not cheapest! What went wrong?

What follows – keep for next slide. Problem with h(A) = 6. Overestimating the expense. (Same problem for h(S).)

Estimates need to be \leq actual costs.

Is A* optimal?

What is the problem?

³Graph example: Dan Klein and Pieter Abbeel

Notes

Try to answer the question before going to the next slide.

1. S

$$- f(S) = g(S) + h(S) = 0 + 7 = 7$$

- expanding/poping this one and crossing out (removing from frontier)

2. $S \rightarrow A$

$$- f(A) = g(A) + h(A) = 1 + 6 = 7$$

- 3. $S \rightarrow G$
 - f(G) = g(G) + h(G) = 5 + 0 = 5
 - This is now cheapest on the frontier. I pop/expand and I'm done.

Ooops! That's not cheapest! What went wrong?

What follows – keep for next slide. Problem with h(A) = 6. Overestimating the expense. (Same problem for h(S).)

Estimates need to be \leq actual costs.

What is the right h(A)?

Notes

 $h(A) \leq 3$ it means less than the actual cost of going from A to goal. Heuristic must not be overly pesimistic. B is correct.

Negative h(n) does not break the admissibility property but h(Goal) = 0 must be always kept. For a discussion, see, e.g.

https://stackoverflow.com/questions/30067813/are-heuristic-functions-that-produce-negative-values-inadmissible

Admissible heuristics

A heuristic function h is admissible if:

 $\begin{array}{rcl} h(n) & \leq & h^*(n) \\ h(\text{Goal}) & = & 0 \end{array}$

Notes -

where $h^*(n)$ is the true cost of going from *n* to the nearest goal.

Optimality of A* tree search

A* is optimal if h(n) is admissible.

Notes -

Notes

- 1. -f(S) = g(S) + h(S) = 0 + 2 = 2- expanding/poping this one and crossing out (removing from frontier); explored set: S
- 2. $S \to A$; f(A) = g(A) + h(A) = 1 + 4 = 5
- 3. $S \to B$; f(B) = g(B) + h(B) = 1 + 1 = 2
- 4. B is cheapest on the frontier. Expanding and removing from frontier; explored set: S, B
- 5. $B \to C$; f(C) = g(C) + h(C) = 3 + 1 = 4
- 6. C is cheapest on the frontier. Expanding and removing from frontier; explored set: S, B, C
- 7. $C \to G$; f(G) = f(G) + h(G) = 6 + 0 = 6
- 8. A is cheapest on the frontier. Expanding and removing from frontier; explored set: S, A, B, C

9.
$$A \to C$$
; $f(C) = f(C) + h(C) = 2 + 1 = 3$

- 10. C is cheapest on the frontier. But, it's on explored set! Can't be expanded.
- 11. Moving on to G, expanding and finishing.

Ooops! That's not cheapest! $cost(S \rightarrow B \rightarrow C \rightarrow G) = 6$; $cost(S \rightarrow A \rightarrow C \rightarrow G) = 5$ What went wrong?

Graph example: Dan Klein and Pieter Abbeel.

Notes

Ooops! That's not cheapest! $cost(S \rightarrow B \rightarrow C \rightarrow G) = 6$; $cost(S \rightarrow A \rightarrow C \rightarrow G) = 5$ What went wrong?

What is the proper h(A)?

22 / 25

As it will be explained in the next slides: $h(A) \le c(A, C) + h(C) = 2$ $h(S) \le c(S, A) + h(A)$ it means $h(A) \ge h(S) - c(A, S) = 1$

Our heuristic was admissible.

With *tree search* it would have worked. It would have expanded C and found the alternative, cheaper path. For graph search, the problem is the $A \rightarrow C \rightarrow G$ subgraph where the *consistent* heuristic condition is violated. The general condition means we have two constraints for (A) for this particuar graph:

For graph search, the problem is the $A \to C \to G$ subgraph where the *consistent* heuristic condition is violated. The general condition means we have two constraints for (*A*) for this particuar graph:

Optimality of A*

- admissible h for tree search
- consistent h for graph search
- What about UCS?
- Are all consistent heuristics also admissible? h(A) − h(C) ≤ cost(A → C)

Notes -

Optimality of A*

- admissible h for tree search
- consistent h for graph search
