RANSAC
Robust Model Estimation
From Data Contaminated By Outliers

Lecturer: Jiří Matas
Authors: Ondřej Chum, Jiří Matas, Ondřej Drbohlav
Czech Technical University in Prague

Last update: March 2021
Talk outline

- Standard Single Class Single Instance Fitting Problem (SCSI)

- Robust Single Class Single Instance Fitting Problem (R-SCSI)

- Single Class Multiple Instance Fitting Problem (SCMI)

- Multiple Class Multiple Instance Fitting Problem (MCMI)
Single/Multi-Class Single/Multi-Instance Fitting Applications

- detection of geometric primitives
- epipolar geometry estimation
- detection of planar surfaces
- multiple motion segmentation
- Interpretation of lidar scans
What is RANSAC?

- RANSAC = RANdom SAmple Consensus

**Example**: Finding a line in 2D
- Not all input points are on the line.
- Finding a line implicitly divides points to **inliers** (=those on a line) and **outliers** (=those not on a line)
- Due to noise, “on a line” actually means inside a narrow strip around the line
Example: Line Fitting

First, let us introduce a line parametrization and define the “strip around the line” formally:

- Line parameters: $\phi \in [0, \pi[, \; r \in \mathbb{R}$
- Point $x = (x, y)$ on the line:
  \[ x \cos \phi + y \sin \phi = r \]
  \[ \iff x \cdot (\cos \phi, \sin \phi) = r \]
- Signed distance $\rho(p)$ of point $p$ from the line:
  \[ \rho(p) = p \cdot (\cos \phi, \sin \phi) - r \]
- Point $p$ inside a strip of half-width $\sigma$:
  \[ |\rho(p)| \leq \sigma \]

Note: $n = (\cos \phi, \sin \phi)$
(thus $\|n\| = 1$)
Line Fitting, Inliers Only: Easy!

Data points

\[ \mathcal{X} = \{x_j, j = 1, 2, \ldots, N_p\} \]

\[ (x_j \in \mathbb{R}^2) \]

Find the line which

“best fits” these points.
Line Fitting, Inliers Only: Easy!

Data points
\[ \mathcal{X} = \{\mathbf{x}_j, j = 1, 2, ..., N_p\} \]
\[ (\mathbf{x}_j \in \mathbb{R}^2) \]

Find the line which “best fits” these points.

Optimization: Find best line with parameters \( \theta^* \):
\[ \theta^* = \arg\min_{\theta} \sum_{\mathbf{x} \in \mathcal{X}} f(\mathbf{x}, \theta) \]

For \( f_{LSQ}(\mathbf{x}, \theta) = [\rho(\mathbf{x})]^2 \)

This is easily solvable by Singular Value Decomposition (SVD)
General Case with Outliers, Example 1

Example 1

Least squares fit
General Case with Outliers, Example 2

Example 2

Least squares fit
General Case with Outliers, Robust Cost Function

- $\mathcal{X} = \{x_j\}_{j=1}^{N_p}$ set of data points

Find:

$$\theta^* = \arg\min_\theta \sum_{x \in \mathcal{X}} f(x, \theta)$$

$$\theta = (r, \phi)$$

- No outliers: $f_{LSQ}(x, \theta) = [\rho(x)]^2$

- For robust fitting, use instead:

$$f_{\text{RANSAC}}(x, \theta) = \begin{cases} 0, & \text{if } |\rho(x)| \leq \text{threshold } \sigma \\ \text{const}, & \text{otherwise} \end{cases}$$

- Such cost function is non-convex (and the optimization task is to minimize the number of outliers)

- How to find optimal line parameters?
Select sample of $m$ points at random (here $m=2$)
RANSAC

Select sample of $m$ points at random

**RANSAC** [Fischler and Bolles 1981]

Input: \( \mathcal{X} = \{x_j\}_{j=1}^N \) data points

- \( e(S) = \theta \) estimates model parameters \( \theta \) given sample \( S \subseteq \mathcal{X} \)

- \( f(x, \theta) = \begin{cases} 0, & \text{if distance to model } \leq \text{ threshold } \sigma \\ 1, & \text{otherwise} \end{cases} \)

\[ \Rightarrow J(\theta) = \sum_{x \in \mathcal{X}} f(x, \theta) \text{ is } \#\text{outliers} \]

\( \eta \) – required confidence in the solution, \( \sigma \) – outlier threshold

Output: \( \theta^* \) parameter of the model minimizing the cost function

1: \( \text{iter} \leftarrow 0, J^* \leftarrow \infty \)
2: **repeat**
3: Select *random* \( S \subseteq \mathcal{X} \) (sample size \( m = |S| \))
4: Estimate parameters \( \theta = e(S) \)
5: Evaluate \( J(\theta) = \sum_{x \in \mathcal{X}} f(x, \theta) \)
6: If \( J(\theta) < J^* \) then
   - \( \theta^* \leftarrow \theta, J^* \leftarrow J(\theta) \)
7: \( \text{iter} \leftarrow \text{iter} + 1 \)
8: **until** \( P(\text{better solution exists}) = f(|\mathcal{X}|, J^*, \text{iter}) < 1 - \eta \)
9: Compute \( \theta^* \) from all inliers \( \mathcal{X}_{in} \): \( \theta^* \leftarrow \text{LocalOptimization}(\mathcal{X}_{in}, \theta^*) \)
RANSAC – how many samples?

- \( N \) Number of points
- \( Q \) Number of inliers, \( Q = N - J^* \)
- \( m \) Size of sample
- \( \epsilon = Q/N \) Inlier ratio

Probability of all-inlier (uncontaminated) sample:

\[
P(\text{inlier sample}) = \frac{\binom{Q}{m}}{\binom{N}{m}} = \frac{Q(Q-1)...(Q-m+1)}{N(N-1)...(N-m+1)} \approx \epsilon^m
\]

Mean time for hitting all-inliers sample is proportional to \( 1/P \).
RANSAC – how many samples?

- How about this formulation:
  - Set the number of samples \( k \) such that at least one pair of points from the line has been hit with probability larger than \( \eta \)
  - Equivalently ... such that no pair of points from the line has been hit with probability lower than \( 1 - \eta \)

- \( Q \) Number of inliers, \( Q = N - J^* \)
- \( m \) Size of sample
- \( \epsilon = Q/N \) Inlier ratio

Probability of all-inlier (uncontaminated) sample:

\[
P(\text{inlier sample}) = \binom{Q}{m} / \binom{N}{m} = \frac{Q(Q-1)...(Q-m+1)}{N(N-1)...(N-m+1)} \approx \epsilon^m
\]

The required confidence in solution:

\[
P(\text{bad model} \ k \ \text{times}) = (1 - P(\text{inlier sample}))^k < 1 - \eta
\]

Finding the solution with confidence \( \eta \) therefore requires at least \( k \) samples:

\[
k \geq \log(1 - \eta) / \log(1 - \epsilon^m)
\]
RANSAC termination – how many samples?

- $m$  Size of sample
- $\epsilon = Q/N$  Inlier ratio
- $\eta$  Confidence
- $k$  required number of samples

Probability of all-inlier (uncontaminated) sample:

$$k \geq \log(1 - \eta) / \log \left(1 - \epsilon^m\right)$$
## RANSAC termination - How many samples?

**Inlier ratio** $\epsilon = \frac{Q}{N} \%$

Computed for confidences $\eta = 0.95$ (first row in each cell), $\eta = 0.99$ (second row) and $\eta = 0.999$ (third row)
RANSAC Notes

Pros:
● extremely popular (>17000 citations in Google Scholar)
● used in many applications
● percentage of inliers not needed and not limited
● a probabilistic guarantee for the solution
● mild assumptions: $\sigma$ known

Cons:
● slow if inlier ratio low
● It was observed experimentally that RANSAC takes several times longer than theoretically expected. This is due to noise – not every all-inlier sample generates a good hypothesis:

$$P(\text{inlier sample}) \neq P(\text{good model estimate})$$
RANSAC Variants

- **Cost function**: MLESAC, Huber loss, ...

- **Outlier threshold** $\sigma$ (how to set it in advance? Or, how to avoid setting it?): Least median of Squares, MINPRAN, MAGSAC, ...

- **Correctness of the results. Degeneracy.**
  Solution: DegenSAC.

- **Accuracy** (parameters are estimated from minimal samples).
  Solution: Locally Optimized RANSAC

- **Speed**: Running time grows with number of data points, number of iterations (polynomial in the inlier ratio)
  Addressing the problem:
  R-RANSAC (Randomized evaluation), RANSAC with SPRT (WaldSAC), PROSAC

Comparison with model (100 inliers):
Estimation of (approximate) models with lower complexity (less data points in the sample) followed by LO step estimating the desired model speeds the estimation up significantly.

The estimation of epipolar geometry is up to 10000 times faster when using 3 region-to-region correspondences rather than 7 point-to-point correspondences.

Simultaneous estimation of radial distortion and epipolar geometry with LO is superior to the state-of-the-art in both speed and precision of the model.

Chum, Matas, Obdržálek: Enhancing RANSAC by Generalized Model Optimization, ACCV 2004
LO-RANSAC: Problem Summary

It was observed experimentally that RANSAC takes several times longer than theoretically expected. This is due to the noise – not every all-inlier sample generates a good hypothesis.

By applying local optimization (LO) to the-best-so-far hypotheses:
(i) a near perfect agreement with theoretical performance
(ii) lower sensitivity to noise and poor conditioning.

The LO is shown to be executed so rarely, \(\log(\text{iter})\) times, that it has minimal impact on the execution time.

Chum, Matas, Kittler: Locally Optimized RANSAC, DAGM 2003
RANSAC – Time Complexity

Repeat $k$ times ($k$ is a function of sample size $m$, number of inliers $Q$, number of data $N$, and confidence $\eta$)

1. Hypothesis generation
   - Select a sample of $m$ data points
   - Calculate parameters of the model(s)

2. Model verification
   - Find the support (consensus set) by verifying all $N$ data points

Running time:

$$ t = k(t_M + \overline{m}_sN) $$

*Note 1*: unit of time = time to evaluate 1 point ($\Rightarrow$ evaluating $N$ points takes time $N$).

*Note 2*: number of models per sample for our toy, line fitting example, is equal to 1. Some tasks (e.g. epipolar geometry estimation) generate different number of solutions (models) per sample, depending on the sample data. 7-point algorithm, for example, generates up to 3 models.
Randomised RANSAC (R-RANSAC) [Matas, Chum 02]

Repeat until termination condition is met:
1. Hypothesis generation (as before)
2a. Model pre-verification $T_{d,d}$ test:
   Evaluate $d \ll N$ data points, reject the model if not all $d$ data points are consistent with the model
2b. Model verification
   Verify the rest of the data points if pre-verification test was successful

Example ($d=1$)
1. Generate a model (sample 2 points)
2a. Sample another point •
   Does it fall within threshold?
   No. Go to 1.
Randomised RANSAC (R-RANSAC) [Matas, Chum 02]

Repeat until termination condition is met:
1. Hypothesis generation (as before)
2a. Model pre-verification $T_{d,d}$ test:
   Evaluate $d \ll N$ data points, reject the model if not all $d$ data points are consistent with the model
2b. Model verification
   Verify the rest of the data points if pre-verification test was successful

Example ($d=1$)
1. Generate a model (sample 2 points)
2a. Sample another point
   Does it fall within threshold?
   Yes.
2b. Verify all other points.
R-RANSAC Example, Running Time Analysis

Find a line in 2D points. \( N=10k, \, \epsilon = 0.1 \) (10\% inliers.)

**RANSAC:**

Probability of selecting 2 ‘good’ points is \( \epsilon^2 \).

Average number of samples to find a good model is \( 1/\epsilon^2 = 100 \).

For each model, \( N \) points are verified.

Total number of evaluations is \( 100N = 1M \)

![Graph showing 2D points and a line](image-url)
R-RANSAC Example, Running Time Analysis

Find a line in 2D points. \( N = 10k, \epsilon = 0.1 \) (10\% inliers.)

**R-RANSAC** \((d=1)\):

- Probability of selecting 2 ‘good’ points is \( \epsilon^2 \).
- Probability of selecting inlier point for pre-verification is \( \epsilon \).
- Average number of samples to find a good model is \( \frac{1}{\epsilon^3} = 1000 \).
- Probability of a random point passing pre-verification test for a ‘bad’ model is \( \delta = 0.03 \).

In 1000 samples:
- \( 1000 \cdot \epsilon^2 = 10 \) ‘good’ models
  - \( 10 \cdot \epsilon = 1 \) passes pre-verification
  - \( 10 \cdot (1 - \epsilon) = 9 \) fails pre-verification
- \( 1000 \cdot (1 - \epsilon^2) = 990 \) ‘bad’ models
  - \( 990 \cdot \delta = 30 \) passes pre-verification
  - \( 990 \cdot (1 - \delta) = 960 \) fails pre-verification

Total number of evaluations, on average:
- \( 1N \) (good model, point accepted)
- + 9 (good model, point rejected)
- + 30N (bad model, point accepted)
- + 960 (bad model, point rejected)

\( \approx 311k \)
R-RANSAC Example, Running Time Analysis

Find a line in 2D points. \( N=10k, \epsilon = 0.1 \) (10% inliers.)

**R-RANSAC** \((d=2)\):

- Probability of selecting 2 ‘good’ points is \( \epsilon^2 \).
- Probability of selecting 2 inlier points for pre-verification is \( \epsilon^2 \).
- Average number of samples to find a good model is \( 1/\epsilon^4 = 10000 \).

In 10000 samples:
- \( 10000 \cdot \epsilon^2 = 100 \) ‘good’ models
- \( 100 \cdot \epsilon^2 = 1 \) passes pre-verification
- \( 100 \cdot (1-\epsilon) = 99 \) fails pre-verification
- \( 10000 \cdot (1-\epsilon^2) = 9900 \) ‘bad’ models
- \( 9900 \cdot \delta^2 = 9 \) passes pre-verification
- \( 990 \cdot (1-\delta^2) = 9891 \) fails pre-verification

**Note:** For this case, \( d=2 \) is optimal (fastest)
Randomised RANSAC (R-RANSAC) [Matas, Chum 02]

Speeds up RANSAC; “Randomised” stands for *randomised verification*

**Running time** (RANSAC $\rightarrow$ R-RANSAC):

$$ t = k(t_M + \bar{m}_s N) \quad \rightarrow \quad t = \frac{k}{1 - \alpha}(t_M + \bar{m}_s V) $$

- $V$ - average number of data points verified
- $\alpha$ – probability that a good model is rejected by $T_{d,d}$ test
- $k$ – *number of samples* (function of sample size, inlier ratio and confidence)
Optimal Randomised Strategy

Model Verification employing Sequential Decision Making

\[ H_g: \ P(x_i = 1 | H_g) \geq \varepsilon \]
\[ H_b: \ P(x_i = 1 | H_b) = \delta \]
\[ x_i = 1 \quad x_i \text{ is consistent with the model} \]

where

\( H_g \) - hypothesis of a ‘good’ model (≈ from an uncontaminated sample)
\( H_b \) - hypothesis of a ‘bad’ model (≈ from a contaminated sample)
\( \delta \) - probability of a data point being consistent with an arbitrary model

Optimal (the fastest) test that ensures with probability \( \alpha \) that that \( H_g \) is not incorrectly rejected is the Sequential probability ratio test (SPRT) [Wald47]
SPRT [simplified from Wald 47]

Likelihood ratio

\[ \lambda_i = \prod_{j=1}^{i} \frac{P(x_j | H_b)}{P(x_j | H_g)} \]

Set (compute) threshold \( A \). Set \( j=1 \)
1. Select a point and check whether it is consistent with model
2. Update likelihood ratio
3. If \( \lambda_j > A \) decide the model is ‘bad’, else increment \( j \)
4. If \( j > N \) (total number of points) decide model is ‘good’, else go to 1.

Properties of SPRT:
1. probability of rejecting a “good” model \( \alpha < 1/A \)
2. average number of verifications \( V = C \log(A) \)

\[ C \approx \left( P(0 | H_b) \log \frac{P(0 | H_b)}{P(0 | H_g)} + P(1 | H_b) \log \frac{P(1 | H_b)}{P(1 | H_g)} \right)^{-1} \]

\[ C \approx ((1 - \delta) \log \frac{1-\delta}{1-\varepsilon} + \delta \log \frac{\delta}{\varepsilon})^{-1} \]
SPRT properties

Probability of rejecting a “good” model $\alpha=1/A$

$$\lambda_i = \prod_{j=1}^{i} \frac{P(x_j|H_b)}{P(x_j|H_g)} = \frac{P(x|H_b)}{P(x|H_g)} \frac{P(x_1, \ldots, x_i)}{P(x_1, \ldots, x_i)}$$

If $\lambda_i > A$ then $P(x|H_g) < P(x|H_b)/A$, therefore

$$\alpha = \int_{\lambda_i > A} P(x|H_g)dx < \int_{\lambda_i > A} P(x|H_b)/Adx =$$

$$= \frac{1}{A} \int_{\lambda_i > A} P(x|H_b)dx \leq \frac{1}{A} \int P(x|H_b)dx = \frac{1}{A}$$
WaldSAC

Running time

\[ t(A) = \frac{k}{(1 - 1/A)}(t_M + \overline{m}_SC \log A) \]

In sequential statistical decision problem decision errors are traded off for time. These are two incomparable quantities, hence the constrained optimization.

In WaldSAC, decision errors cost time (more samples) and there is a single minimised quantity, time \( t(A) \), a function of a single parameter \( A \).
Optimal test (optimal $A$) given $\epsilon$ and $\delta$

Optimal $A^*$

$$A^* = \arg \min_A t(A)$$

Optimal $A^*$ found by solving

$$\frac{\partial t}{\partial A} = 0$$

$$A^* = \frac{t_M}{m_s C} + 1 + \log A^*$$

$$A^* = \lim_{n \to \infty} A_n$$

Computed in several iterations:

$$A_0 = \frac{t_M}{m_s C} + 1, \quad A_{n+1} = \frac{t_M}{m_s C} + 1 + \log A_n$$
Note: the Wald’s test is equivalent to series of $T(d, c)$, where $c = \left[\frac{(\log A - d \log \lambda_1)}{\log \lambda_0}\right]$

Randomised Verification in RANSAC: Conclusions

- The same confidence $\eta$ in the solution reached faster (data dependent, $\approx 10\times$)
- No change in the character of the algorithm, it was randomised anyway.
- Optimal strategy derived using Wald’s theory for known $\varepsilon$ and $\delta$.
- Results with $\varepsilon$ and $\delta$ estimated during the course of RANSAC are not significantly different. Performance of SPRT is insensitive to errors in the estimate.
  - $\delta$ can be learnt, an initial estimate can be obtained by geometric consideration
  - Lower bound on $\varepsilon$ is given by the best-so-far support
PROSAC – PROgressive SAmple Consensus

- Not all correspondences are created equally
- Some are better than others
- Sample from the best candidates first

Sample from here
Draw $T_l$ samples from $(1 \ldots l)$
Draw $T_{l+1}$ samples from $(1 \ldots l+1)$

Samples from $(1 \ldots l)$ that are not from $(1 \ldots l+1)$ contain $l+1$

Draw $T_{l+1} - T_l$ samples of size $m-1$ and add $l+1$
Degenerate Configurations

The presence of degenerate configuration causes RANSAC to fail in estimating a correct model, instead a model consistent with the degenerate configuration and some outliers is found.

The DEGENSAC algorithm handles scenes with:

- all points in a single plane
- majority of the points in a single plane and the rest off the plane
- no dominant plane present

No a-priori knowledge of the type of the scene is required

Chum, Werner, Matas: Epipolar Geometry Estimation unaffected by dominant plane, CVPR 2005
**GC-RANSAC** [Barath and Matas, CVPR 2018]

**Input:** $\mathcal{X} = \{x_j\}_{j=1}^N$

$e(S) = \theta$ estimates model parameters $\theta$, given sample $S \subseteq \mathcal{X}$

$f(x, \theta) = \begin{cases} 
0, & \text{if distance to model } \leq \text{threshold} \\
1, & \text{otherwise}
\end{cases}$

**Output:** $\theta^*$ parameter of the model minimizing the cost function

1. $\text{iter} = 0$, $J^* = \infty$
2. **repeat**
3. Select random $S \subseteq \mathcal{X}$ (sample size $m = |S|$)
4. Estimate parameter $\theta = e(S)$
5. Evaluate $J(\theta) = \sum_{x \in \mathcal{X}} f(x, \theta)$
6. If $J(\theta) < J^*$ then
   7. $\theta^*, L^* \leftarrow \text{arg min}_{\theta, L} \sum_{x \in \mathcal{X}} f(x, \theta) + \lambda \sum_{(x, y) \in A} \lceil L(x) \neq L(y) \rceil$
8. $J^* \leftarrow J(\theta^*)$
9. $\text{iter} \leftarrow \text{iter} + 1$
10. **until** $P(\text{better solution exists}) = f(|\mathcal{X}|, J^*, \text{iter}) < \mu$

Run graph-cut, if a so-far-the-best solution is found.
Figure 1: The proposed graph-cut based local optimization converging from a “not-all-inlier” sample, i.e. it is contaminated by an outlier, to the desired model. (a) The input data points, (b) RANSAC-like sampling and model fitting, (c) computation of model support, e.g. counting the inliers, (d) considering spatial proximity by graph-cut, (e-f) iterated local optimization using least-squares fitting and graph-cut.
