# **Constraint-Handling in Evolutionary Algorithms**

### Jiří Kubalík

Czech Institute of Informatics, Robotics and Cybernetics CTU Prague

http://cw.felk.cvut.cz/doku.php/courses/a0m33eoa/start

### **Motivation**

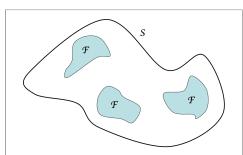

The general nonlinear programming problem (NLP) can be formulated as solving the objective function

Minimize 
$$f(x)$$
,  $x = [x_1, ..., x_n]^T$ ; subject to  $g_i(x) \le 0$ ,  $i = 1, 2, ..., m$ ;  $h_j(x) = 0$ ,  $j = 1, 2, ..., p$ ;

where

• x is a vector of n decision variables,

ullet  $\mathcal{F} \subseteq \mathcal{S}$  is the feasible region defined by m inequality and p equality constraints.

When solving NLP with EAs, equality constraints are usually transformed into inequality constraints of the form:

$$|h_j(x)| - \varepsilon \le 0$$

where  $\varepsilon$  is the tolerance allowed.

## **Standard Evolutionary Algorithm**

```
Begin
  t=0
Initialize P(t)
Evaluate P(t)
while (not termination-condition) do
begin
  t=t+1
  Select P(t) from P(t-1)
  Recombine
  Evaluate P(t)
  end
End
```

Evolutionary Algorithms (EAs) have been found successful in solving a wide variety of optimization problems.

However, **EAs are unconstrained search techniques**. Therefore, it is necessary to incorporate constraints into components of the EA (i.e. the fitness function and genetic operators).

# **Taxonomy of Presented Constraint-Handling Approaches**

- Penalty functions
- Stochastic Ranking
- Special representations and operators
- Multiobjective optimization techniques

### General Form of Fitness Function with Penalty Function

The idea of penalty functions is to transform a constrained optimization problem into unconstrained one by adding certain value to the objective function based on the amount of constraint violation present in the solution:

$$\psi(x) = f(x) + \sum_{i=1}^{m} r_i \times G_i + \sum_{j=1}^{p} r_j \times H_j$$

where  $\psi(x)$  is the new objective function referred to as the **fitness function**,  $G_i$  and  $H_j$  are functions of the constraints violation  $(g_i(x))$  and  $h_j(x)$ , and  $h_j(x)$ , and  $h_j(x)$  are positive constants called **penalty coefficients** or penalty factors.

A common form of  $G_i$ :

$$G_i = \max(0, g_i(x))$$

A common form of  $H_i$ :

$$H_j = |h_j(x)|$$

or

$$H_j = \max(0, g_j(x)), \text{ for } g_j \equiv |h_j(x)| - \varepsilon \leq 0$$

## **Types of Penalty Functions used with EAs**

Four categories of penalty functions based on the way its parameters are being determined:

- Death penalty
- Static penalty
- Dynamic penalty
- Adaptive penalty

### **Death Penalty**

The **rejection of infeasible individuals** is probably the easiest way to handle constraints and it is also computationally efficient, because when a certain solution violates a constraint, it is rejected and generated again.

 The approach is to iterate, generating a new point at each iteration, until a feasible solution is found.

Thus, no further calculations are necessary to estimate the degree of infeasibility of such a solution.

### **Death Penalty**

The **rejection of infeasible individuals** is probably the easiest way to handle constraints and it is also computationally efficient, because when a certain solution violates a constraint, it is rejected and generated again.

The approach is to iterate, generating a new point at each iteration, until a feasible solution is found.

Thus, no further calculations are necessary to estimate the degree of infeasibility of such a solution.

#### Criticism:

- No exploitation of the information from infeasible solutions.
  - Search may "stagnate" in the presence of very small feasible regions.
  - Not advisable, except in the case of problems in which the proportion of feasible region in the whole search space is fairly large.
- A variation that assigns a zero (or very bad) fitness to infeasible solutions may work better in practice.

# **Death Penalty: Relaxed**

Fitness of an individual is determined using:

$$\begin{array}{rcl} f(x) & \text{if the solution is feasible} \\ fitness_i(x) &= & \\ K(1-\frac{s}{m+p}) & \text{otherwise} \end{array}$$

#### where

- s is the number of constraints satisfied, and
- K is a large constant.

If an individual is infeasible,

- its fitness is always worse than a fitness of any other feasible individual and
- its fitness is the same as the fitness of all the individuals that violate the same number of constraints.

### **Static Penalty**

Approaches in which the **penalty coefficients do not depend** on the current generation number, they remain constant during the entire evolution.

The approach proposed in [Homaifar94] defines **levels of violation** of the constraints (and **penalty coefficients** associated to them):

$$fitness(x) = f(x) + \sum_{i=1}^{m+p} (R_{k,i} \times (max[0, g_i(x)])^2)$$

where  $R_{k,i}$  are the penalty coefficients used, m+p is the total number of constraints, f(x) is the objective function, and  $k=1,2,\ldots,l$ , where l is the number of levels of violation defined by user

### **Static Penalty**

Approaches in which the **penalty coefficients do not depend** on the current generation number, they remain constant during the entire evolution.

The approach proposed in [Homaifar94] defines **levels of violation** of the constraints (and **penalty coefficients** associated to them):

$$fitness(x) = f(x) + \sum_{i=1}^{m+p} (R_{k,i} \times (max[0, g_i(x)])^2)$$

where  $R_{k,i}$  are the penalty coefficients used, m+p is the total number of constraints, f(x) is the objective function, and  $k=1,2,\ldots,l$ , where l is the number of levels of violation defined by user

#### Criticism:

■ The weakness of the method is the high number of parameters: for m constraints and l levels of violation for each, the method requires m(2l+1) parameters in total.

For m=5 and l=4, we need 45 parameters!!!

Clearly, the results are heavily parameter dependent.

 Presented method requires prior knowledge of the degree of constraint violation present in the problem (to define the levels of violation), which might not be easy to obtain in real-world applications.

- Penalty coefficients are difficult to generalize. They are, in general, problem-dependent.
- Anyway, it is not a good idea to keep the same penalty coefficient along the entire evolution.
  The population evolves, so why should the coefficients that bias the search direction be static?

### **Dynamic Penalty**

Penalty functions in which the current generation number is involved in the computation of the corresponding penalty coefficients.

**Typically**, the penalty coefficients are defined in such a way that **they increase over time** pushing the search towards the feasible region.

The approach from [Joines94] evaluates individuals as follows:

$$fitness(x) = f(x) + (C \times t)^{\alpha} \times SVC(x)$$

where t is the generation number and C and  $\alpha$  are user-defined constants; recommended values are C=0.5 or 0.05,  $\alpha=1$  or  ${\bf 2}$ .

SVC(x) is defined as:

$$SVC(x) = \sum_{i=1}^{m} G_i(x) + \sum_{j=1}^{p} H_j(x)$$

where  $G_i(x)$  and  $H_j(x)$  are functions of the constraints violation  $(g_i(x))$  and  $h_j(x)$ .

**Step-wise non-stationary penalty function** increases the penalty proportionally to the generation number. The goal is to allow the GA to explore more of the search space before confining it to the feasible region.

### **Dynamic Penalty: Criticism**

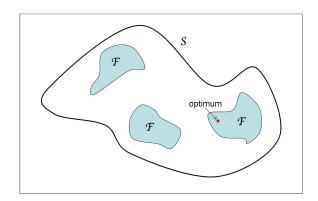

- It is difficult to derive good dynamic penalty functions in practice. The presented approach is sensitive to changes in values of  $\alpha$  and C and there are no guidelines for choosing proper values for particular problem.
- If a bad penalty coefficient is chosen, the EA may converge to either non-optimal feasible solutions (if the penalty is too high) or to infeasible solutions (if the penalty is too low).
- No constraint normalization technique is used, thus certain constraint may undesirably dominate the whole penalty value.

## **Adaptive Penalty: Motivation**

Let's assume the penalty fitness function of the following form:

$$\psi(x) = f(x) + r_g \times \sum_{i=1}^{m+p} G_i(x)^2$$

Deciding on an optimal (or near-optimal) value  $r_q$  is a difficult optimization problem itself.

- If  $r_g$  is **too small**, an infeasible solution may not be penalized enough. Hence, infeasible solutions may be evolved by an EA.
- If  $r_g$  is **too large**, a feasible solution is likely to be found, but could be of a poor quality. A large  $r_g$  discourages the exploration of infeasible regions.

This is inefficient for problems where feasible regions in the whole search space are disjoint and/or the constraint optimum lies close to the boundary of the feasible domain.

Reasonable exploration of infeasible regions may act as bridges connecting feasible regions.

How much exploration of infeasible regions  $(r_q =?)$  is reasonable?

- It is problem dependent.
- lacktriangle Even for the same problem, different stages of evol. search may require different  $r_g$  values.

# **Adaptive Penalty**

- GA with non-linear penalty function.
- Adaptive Segregational Constraint Handling EA (ASCHEA).
- Stochastic Ranking.

## **GA** with Non-linear Penalty Function

The method introduced in [Hadj-Alouane92] uses adaptive penalty function that takes a feedback from the search process

$$fitness_i(x) = f_i(x) + r_g(t) \sum_{i=1}^{m+p} G_i(x)^2$$

where  $r_q(t)$  is updated every generation according to the following rule:

$$r_g(t+1) = \begin{cases} (1/\beta_1) \cdot r_g(t), & \text{if case } \#1 \\ \beta_2 \cdot r_g(t), & \text{if case } \#2 \\ r_g(t), & \text{otherwise,} \end{cases}$$

#### where

- case #1 the situation where the best individual in the last k generations was **always** feasible;
- case #2 the situation where the best individual in the last k generations was **never feasible**;
- $\beta_1, \beta_2 > 1$ , and  $\beta_1 \neq \beta_2$  (to avoid cycling).

#### Remarks:

■ The penalty component for the generation t+1 is decreased if the feasible region **was** effectively sampled within last k generations;

- The penalty component for the generation t+1 is increased if the feasible region was not effectively sampled within last k generations;
- It tries to avoid having either an all-feasible or an all-infeasible population.
- The problem is how to choose a proper generational gap (k) and the values of  $\beta_2$  and  $\beta_1$ .

### Adaptive Segregational Constraint Handling EA - ASCHEA

The main idea in ASCHEA [Hamida00] is to maintain both feasible and infeasible individuals in the population, at least when it seems necessary.

It proposes adaptive mechanisms at the population level for constraint optimization based on three main components:

- 1. Adaptive penalty function takes care of the penalty coefficients according to the proportion of feasible individuals in the current population.
- 2. Constraint-driven mate selection used to mate feasible individuals with infeasible ones and thus explore the region around the boundary of the feasible domain.
- 3. **Segregational replacement strategy** used to favor a given number of feasible individuals in the population.

# **ASCHEA: Adaptive Penalty**

Let's assume the penalty function of the following form:

$$penal(x) = \alpha \sum_{i=1}^{m+p} G_i(x)$$

The penalty coefficient  $\alpha$  is adapted based on the desired proportion of feasible solutions in the population,  $\tau_{target}$ , and the actual proportion at generation t,  $\tau_{t}$ :

if
$$(\tau_t > \tau_{target})$$
  $\alpha(t+1) = \alpha(t)/fact$   
otherwise  $\alpha(t+1) = \alpha(t) * fact$ 

where fact > 1 is a user-defined parameter, a recommended value is around 1.1.

A recommended value of  $\tau_{target}$  is around 0.6.

### **ASCHEA: Constraint-driven Mate Selection**

Selection mechanism chooses the mate of feasible individuals to be infeasible.

• Only applied when too few (w.r.t  $\tau_{target}$ ) feasible individuals are present in the population.

More precisely, to select the mate  $x_2$  for a first parent  $x_1$ :

if  $(0 < \tau_t < \tau_{target})$  and  $(x_1 \text{ is feasible})$  select  $x_2$  among infeasible solutions only otherwise select  $x_2$  according to fitness

## **ASCHEA: Segregational Replacement**

Deterministic replacement mechanism used in ES-like scheme that should further **enhance the chances of survival of feasible individuals**.

Assume a population of  $\mu$  parents, from which  $\lambda$  offspring are generated. Depending on the replacement scheme

- ullet  $\mu$  individuals out of  $\lambda$  offspring in case of the  $(\mu, \lambda)$ -ES, or
- ullet  $\mu$  individuals out of  $\lambda$  offspring plus  $\mu$  parents in case of the  $(\mu + \lambda)$ -ES

are selected to the new population in the following way:

- 1. First, feasible solutions are selected without replacement based on their fitness, until  $\tau_{select} * \mu$  have been selected, or no more feasible solution is available.
- 2. The population is then filled in using **standard deterministic selection on the remaining individuals**, based on the penalized fitness.

Thus, a user-defined proportion of  $\tau_{select}$  feasible solutions is considered superior to all infeasible solutions.

A recommended value of  $\tau_{select}$  is around 0.3.

### **ASCHEA: Niching**

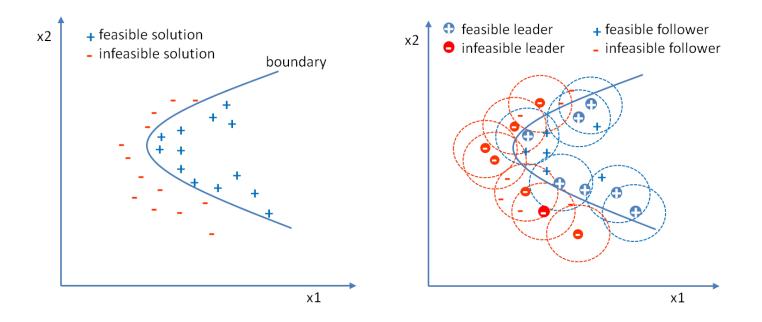

**Niching** – helps to better handle multimodal functions.

- lacktriangle a niche defined as a hypersphere around a good individual of a diameter r
- a niche has its **capacity**,  $niche_{capacity}$ , defining the maximal number of **leaders** in a niche (including its central individual)
- other individuals falling within the niche, called followers, are discarded from further selections

input: population sorted from the best to the worst individual)

```
for i=1 to \mu
1.
              if \overrightarrow{x_i} \notin followers
                     add \overrightarrow{x_i} to leaders
                     nbLeaders = 1
4.
5.
                     for j = i + 1 to \mu
                     if \overrightarrow{x_i} \notin followers and distance(\overrightarrow{x_i}, \overrightarrow{x_i}) < r
6.
7.
                            if nbLeaders < niche_{capacity}
                                   nbLeaders + +
                            else
                                   add \overrightarrow{x_i} to followers
10.
```

# **ASCHEA:** Niching with $niche_{capacity} = 2$

### Niching is used in segregational replacement

- the replacement is first applied on the leaders,
- then on the followers, if necessary.

### **ASCHEA: Niching**

#### Adaptation of the niche radius r

- $au_{clear}$  is a desired proportion of *leaders* (or *followers*) in the population, typically  $au_{clear} = 0.4$
- ullet  $au_{leaders}$  and  $au_{followers}$  are the proportions of leaders and followers in the population at the generation t.

where fact > 1 is a user-defined parameter, a recommended value is around 1.1.

### **ASCHEA: Conclusions**

- Feasibility elitism as soon as a feasible individual appears, it can only disappear from the population by being replaced by a better feasible solution, even if the penalty coefficient reaches very small value.
- Constraint-driven mate selection accelerates the movement toward the feasible region of infeasible individuals, and helps to explore the region close to the boundary of the feasible domain.
- **Adaptability** the penalty adaptation as well as the constraint-driven mate selection are activated based on the actual proportion of feasible solutions in the population.

Let's assume the penalty fitness function of the following form:

$$\psi(x) = f(x) + r_g \times \sum_{i=1}^{m+p} G_i(x)^2$$

For a given penalty coefficient  $r_g > 0$ , let the ranking of  $\lambda$  individuals be

$$\psi(x_1) \le \psi(x_2) \le \dots \le \psi(x_\lambda),\tag{1}$$

For any given adjacent pair i and i+1 in the ranked order

$$f_i + r_g G_i \le f_{i+1} + r_g G_{i+1}$$
 where  $f_i = f(x_i)$  and  $G_i = G(x_i)$  (2)

we define so called critical penalty coefficient

$$\check{r}_i = (f_{i+1} - f_i)/(G_i - G_{i+1}) \text{ for } G_i \neq G_{i+1}$$
(3)

For given choice of  $r_g \ge 0$ , there are three different cases which may give rise to inequality (2):

- 1.  $f_i \leq f_{i+1}$  and  $G_i \geq G_{i+1}$ : Objective function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < r_g < \check{r}_i$ .
- 2.  $f_i \ge f_{i+1}$  and  $G_i < G_{i+1}$ : Penalty function plays a dominant role in determining the inequality and the value of  $r_q$  should be  $0 < \check{r}_i < r_q$ .
- 3.  $f_i < f_{i+1}$  and  $G_i < G_{i+1}$ : The comparison is nondominated and  $\check{r}_i < 0$ . Neither the objective nor the penalty function can determine the inequality by itself.

For given choice of  $r_g \ge 0$ , there are three different cases which may give rise to inequality (2):

1.  $f_i \leq f_{i+1}$  and  $G_i \geq G_{i+1}$ : Objective function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < r_g < \check{r}_i$ .

Ex.:

$$f_i = 10$$
,  $G_i = 7$   
 $f_{i+1} = 20$   $G_{i+1} = 5$   
 $\check{r}_i = (20 - 10)/(7 - 5) = 5 \implies 0 < r_g < 5$   
 $r_g = 4$ :  $38 \le 40$  the inequality (2) holds  
 $r_g = 6$ :  $52 \nleq 50$  the inequality (2) does not hold

- 2.  $f_i \ge f_{i+1}$  and  $G_i < G_{i+1}$ : Penalty function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < \check{r}_i < r_g$ .
- 3.  $f_i < f_{i+1}$  and  $G_i < G_{i+1}$ : The comparison is nondominated and  $\check{r}_i < 0$ . Neither the objective nor the penalty function can determine the inequality by itself.

For given choice of  $r_g \ge 0$ , there are three different cases which may give rise to inequality (2):

- 1.  $f_i \leq f_{i+1}$  and  $G_i \geq G_{i+1}$ : Objective function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < r_g < \check{r}_i$ .
- 2.  $f_i \ge f_{i+1}$  and  $G_i < G_{i+1}$ : Penalty function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < \check{r}_i < r_g$ .

Ex.:

$$f_i = 20$$
,  $G_i = 5$   
 $f_{i+1} = 10$   $G_{i+1} = 7$   
 $\check{r}_i = (10 - 20)/(5 - 7) = 5 \implies 5 < r_g$   
 $r_g = 4$ :  $40 \nleq 38$  the inequality (2) does not hold  
 $r_q = 6$ :  $50 \leq 52$  the inequality (2) holds

3.  $f_i < f_{i+1}$  and  $G_i < G_{i+1}$ : The comparison is nondominated and  $\check{r}_i < 0$ . Neither the objective nor the penalty function can determine the inequality by itself.

For given choice of  $r_g \ge 0$ , there are three different cases which may give rise to inequality (2):

- 1.  $f_i \leq f_{i+1}$  and  $G_i \geq G_{i+1}$ : Objective function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < r_g < \check{r}_i$ .
- 2.  $f_i \ge f_{i+1}$  and  $G_i < G_{i+1}$ : Penalty function plays a dominant role in determining the inequality and the value of  $r_g$  should be  $0 < \check{r}_i < r_g$ .
- 3.  $f_i < f_{i+1}$  and  $G_i < G_{i+1}$ : The comparison is nondominated and  $\check{r}_i < 0$ . Neither the objective nor the penalty function can determine the inequality by itself.

Ex.:

$$f_i=10$$
,  $G_i=5$  
$$f_{i+1}=20 \quad G_{i+1}=7$$
 
$$\check{r}_i=(20-10)/(5-7)=-5 \quad \Longrightarrow \quad \text{the inequality (2) holds for all } r_g>0$$

The value of  $r_g$  has no impact on the inequality (2) when nondominant and feasible individuals are compared.

The value of  $r_g$  is critical in the first two cases.

For the entire population, the chosen value of  $r_g$  used for comparisons will determine the fraction of individuals dominated by the objective and penalty functions.

It has to be within a certain range  $\underline{r}_q < r_g < \overline{r}_g$ 

- 1.  $\overline{r}_g$  is the **maximum critical penalty** coefficient computed from adjacent individuals ranked only according to the objective function.
- 2.  $\underline{r}_g$  is the **minimum critical penalty** coefficient computed from adjacent individuals ranked only according to the **penalty** function.

Both **bounds are problem dependent** and may **vary from generation to generation** as they are also determined by the current population.

There are three categories of  $r_g$  values

- 1.  $r_g < \underline{r}_q$ : Underpenalization All comparisons are based only on the fitness function.
- 2.  $r_g > \overline{r}_g$ : Overpenalization All comparisons are based only on the penalty function.
- 3.  $\underline{r}_g < r_g < \overline{r}_g$ : All comparisons are based on a combination of objective and penalty functions. This is what a good constraint-handling technique should do **to balance between preserving feasible individuals and rejecting infeasible ones**.

But the optimal  $r_g$  is hard to determine.

All penalty methods can be classified into one of the above three categories. Some methods may fall into different categories during different stages in search

## **Stochastic Ranking: Realization**

### Stochastic Ranking [Runarsson00] characteristics:

- The idea of this approach is that the balance between objective and penalty functions is achieved directly and explicitly.
- It does not require explicit definition of the penalty coefficient  $r_g$  value. Instead, it requires a **user-defined parameter**  $P_f$ , **which determines the balance** between the objective function and the penalty function.

#### Stochastic ranking realization: Bubble-sort-like procedure

- The population is sorted using an algorithm similar to bubble-sort.
- Parameter  $P_f$  specifies a **probability of using only the objective function** for comparisons of infeasible solutions.

If both individuals are feasible then the probability of comparing them according to the objective function is 1. Otherwise, it is  $P_f$ .

The reminder of the comparisons are realized based on the sum of constraint violation.

Recommended range of  $P_f$  values is (0.4, 0.5)

The  $P_f$  introduces the stochastic component to the ranking process, so that **some solutions** may get a good rank even if they are infeasible.

## Stochastic Ranking: Bubble-sort-like Procedure

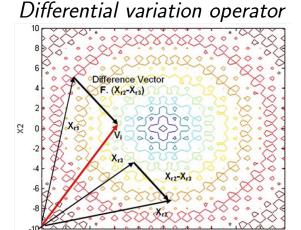

```
1 I_i = j \ \forall \ j \in \{1, \ldots, \lambda\}
    for i = 1 to N do
          for j = 1 to \lambda - 1 do
               sample u \in U(0,1)
               if (\phi(I_i) = \phi(I_{i+1}) = 0) or (u < P_f) then
                 if (f(I_i) > f(I_{i+1})) then
                    swap(I_i, I_{i+1})
                 fi
               else
                 if (\phi(I_i) > \phi(I_{i+1})) then
10
11
                    swap(I_i, I_{i+1})
12
                 fi
13
               fi
14
          od
15
          if no swap done break fi
```

## Stochastic Ranking + DE

### Stochastic ranking coupled to differential evolution

- Solutions (vectors) are ranked with SR before the DE operators are applied.
- The population is split into two sets based on SR
  - 1. Vectors with the highest ranks  $(Q_1)$  from this set the base vector,  $r_1$ , and the vector which determines the search direction,  $r_2$ , are chosen at random.
  - 2. Remaining vectors  $(Q_2)$  the other vector,  $r_3$ , is chosen at random from this set.

# **Stochastic Ranking: Conclusions**

- SR does not use any specialized variation operators.
- ullet SR does not require a priori knowledge about a problem since it does not use any penalty coefficient  $r_g$  in a penalty function.
- The approach is easy to implement.

## **Special Representation and Operators**

**Random keys** – a representation for representing permutations, it is an efficient method for encoding ordering and scheduling problems.

lacktriangle A random key vector of length l consists of l random values (keys) that are floating numbers between zero and one.

Ex.: 
$$\overrightarrow{r}_5 = (0.17, 0.92, 0.63, 0.75, 0.29)$$

Of importance for the interpretation of the random key vector is the position of the keys.
 The positions of the keys in the vector are ordered according to their values in ascending or descending order which gives a permutation of l numbers.

Ex.: Random key vector  $\overrightarrow{r}_5$  can be interpreted as the sequence  $\overrightarrow{r}_5^s = 2 \to 4 \to 3 \to 5 \to 1$ 

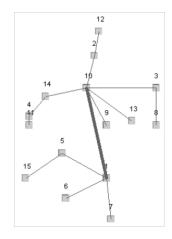

### Properties of the encoding:

- A valid sequence  $\overrightarrow{r}_l^s$  can always be created from the random key vector as long as there are no two keys  $r_i$  and  $r_j$  with the same values.
- There are many possibilities for the construction of each particular sequence (permutation).
- Locality of the random keys is high a small change in the genotype (the vector  $\overrightarrow{r}_l$ ) leads to a small change in the phenotype (the sequence  $\overrightarrow{r}_l^s$ ).
- When using EAs with random keys, all kinds of standard crossover and mutation operators can be used that always produce only valid solutions (i.e. the interpreted permutations).

# Random Keys for the Network Design Problems

#### **Network Design Problem**

- A tree network is defined as a connected graph with n nodes and n-1 links (there are no loops in the tree).
- Between any two nodes there exists exactly one possible path for the flow.
- The goal is to minimize the overall cost for constructing and maintaining the tree network that is calculated by summing-up the cost of all links.

### Encoding tree networks with Network Random Keys (NetKeys) [Rothlauf02]

- The real-valued NetKeys are interpreted as the importance of the link. The higher the value of the allele, the higher the probability that the link is used for the tree.
- Every NetKey vector represents a valid network structure.

## Random Keys for the Network Design Problems

#### Constructing the tree network from the NetKey vector

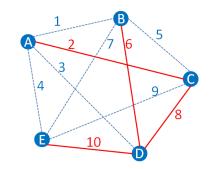

1. Let G be an empty graph with n nodes, and  $\overrightarrow{r}_l^s$  the sequence with length l=n(n-1)/2 that could be constructed from the NetKey vector  $\overrightarrow{r}_l$ . All possible links of G are numbered from 1 to l.

Let 
$$i = 0$$
.

- 2. Let j be the number at the ith position of  $\overrightarrow{r}_{l}^{s}$ .
- 3. If the insertion of the link with number j in G would not create a cycle, then insert the link with number j in G.
- 4. Stop, if there are n-1 links in G.
- 5. Increment i and continue with step 2.

#### Ex.:

link nr.	1	2	3	4	5	6	7	8	9	10

# Approaches based on Evolutionary Multiobjective Optimization

#### General form of multi-objective optimization problem

$$\begin{array}{ll} \mbox{Minimize/maximize} & f_m(x), & m = 1, 2, ..., M; \\ \mbox{subject to} & g_j(x) \geq 0, & j = 1, 2, ..., J; \\ & h_k(x) = 0, & k = 1, 2, ..., K; \\ & x_i^{(L)} \leq x_i \leq x_i^{(U)}, & i = 1, 2, ..., n. \end{array}$$

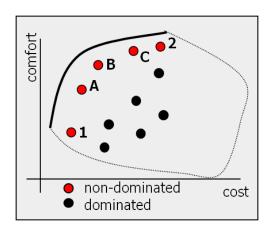

- x is a vector of n decision variables:  $x = (x_1, x_2, ..., x_n)^T$ ;
- $g_j$ ,  $h_k$  are inequality and equality constraints, respectively.

#### Conflicting objectives

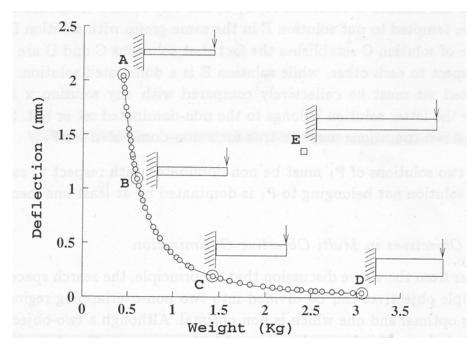

- A solution that is extreme with respect to one objective requires a compromise in other objectives.
- A sacrifice in one objective is related to the gain in other objective(s).

Motivation example: Buying a car

- two extreme hypothetical cars 1 and 2,
- cars with a trade-off between cost and comfort A, B, and C.

### Multiobjective Techniques: Using Pareto Schemes

©Kalyanmoy Deb: Multi-Objective Optimization using Evolutionary Algorithms.

**Pareto dominance**: A solution  $x^{(1)}$  is said to dominate the other solution  $x^{(2)}$ ,  $x^{(1)} \leq x^{(2)}$ , if  $x^{(1)}$  is no worse than  $x^{(2)}$  in all objectives and  $x^{(1)}$  is strictly better than  $x^{(2)}$  in at least one objective.

Solutions A, B, C, D are non-dominated solutions (Pareto-optimal solutions)

Solution E is *dominated* by C and B (E is non-optimal).

## Approaches based on Evolutionary Multiobjective Optimization

Two ways the NLP is transformed into a multiobjective optimization problem

- NLP → Unconstrained Bi-objective Optimization (BOP): Transforms the NLP into an unconstrained bi-objective optimization problem with the objectives being (1) the original objective function and (2) the sum of constraint violation.

The most popular are the MOP approaches.

# Approaches based on Evolutionary Multiobjective Optimization

Two ways the NLP is transformed into a multiobjective optimization problem

- NLP → Unconstrained Bi-objective Optimization (BOP): Transforms the NLP into an unconstrained bi-objective optimization problem with the objectives being (1) the original objective function and (2) the sum of constraint violation.
- NLP → Unconstrained Multiobjective optimization (MOP): Transforms the NLP into an unconstrained multiobjective optimization problem where the original objective function and each constraint are treated as separate objectives.

The most popular are the MOP approaches.

However, multiobjective optimization does not appear to be any easier than constrained optimization since one has to balance different objectives in optimization.

# Multiobjective Techniques: NPGA-based Approach

[Coello02] – Niched-Pareto Genetic Algorithm that uses **binary tournament selection** based on Pareto non-dominance.

• Parameter  $S_r$ , which indicates the minimum number of individuals that will be selected through dominance-based tournament selection.

The remainder,  $1 - S_r$ , will be selected using a purely probabilistic approach.

- **Tournament selection** three possible situations when comparing two candidates
  - 1. Both are feasible. In this case, the candidate with a better fitness value wins.
  - 2. One is infeasible, and the other is feasible. The feasible candidate wins, regardless of its fitness function value.
  - 3. Both are infeasible.
    - (a) Check both candidates whether they are dominated by ind. from the **comparison** set.
    - (b) If one is dominated by the comparison set, and the other is not dominated then the non-dominated candidate wins.
      - Otherwise, the candidate with the lowest amount of constraint violation wins, regardless of its fitness function value.
- Probabilistic selection Each candidate has a probability of 50% of being selected.
- Robust, efficient and effective approach.
