Deep Learning (BEV033DLE) Lecture 10 Learning Representations I

Czech Technical University in Prague

- ◆ Lecture 10: LR-1:
 - Feature Space Representations
 - Word Vectors
 - Similarity / Metric Learning
 - Cross-Modality Representations

Feature Space Representation

- ♦ With good features many tasks are easy:
 - E.g. logistic regression atop of deep features could easily classify butterflies
 - Finding similar objects can be done by nearest neighbor search
- ◆ Suppose we are interested in high-level (semantic tasks). What would we like good features to do?
 - Keep useful information (for all relevant tasks)
 - Discard unnecessary information (view point, lighting, etc.)
 - Similar representations should correspond to semantically similar objects

Examples

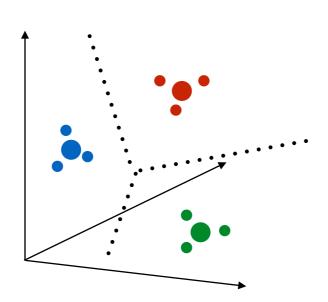

•

m

3

Many tasks become easier if we have good feature

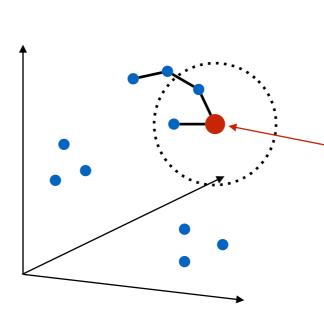

- **♦** Classification:
 - SVM
 - Logistic regression
 - Nearest neighbor classifier
 - Fine-tune the whole model (same or different data)

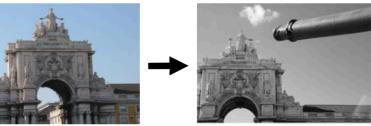

Many tasks become easier if we have good feature

- **♦** Classification:
 - SVM
 - Logistic regression
 - Nearest neighbor classifier
 - Fine-tune the whole model (same or different data)

→ Visual search (retrieval):

- query with an image
- retrieve similar objects or views
- Euclidean nearest neighbor
 - NN graph distance

Many tasks become easier if we have good feature

- Classification:
 - SVM
 - Logistic regression
 - Nearest neighbor classifier
 - Fine-tune the whole model (same or different data)

→ Data exploration

→ Visual search (retrieval):

- query with an image
- retrieve similar objects or views
- Euclidean nearest neighbor
- NN graph distance

[Johnson et al. (2017)]

Word Vectors

- Problem Formulation:
 - Assume a finite vocabulary I, |I| = n
 - \bullet Given a word x, predict nearby words y
- Simple Model:
 - Predict one word by categorical distribution p(y|x)
 - Let $v(x) \in \mathbb{R}^d$ word vector for x
 - x is discrete and not structured parameterize by a matrix V of all word vectors of size $n \times d$: $v(x) = V_{x,:}$
 - Define categorical distribution:

$$p(y|x) = \frac{\exp(u(y)^{\mathsf{T}}v(x))}{\sum_{y'} \exp(u(y')^{\mathsf{T}}v(x))}$$

- ullet Need a different embedding for context words: $u(y) = U_{y,:}$
- Learn via maximum likelihood classification:

$$\max_{U,V} \mathbb{E}_{t,t'} \Big[\log p(y_{t'}|x_t) \Big],$$

where t, t' – nearby positions in the text

Mrs Smith is Turning 60

By JERRY ATRIC

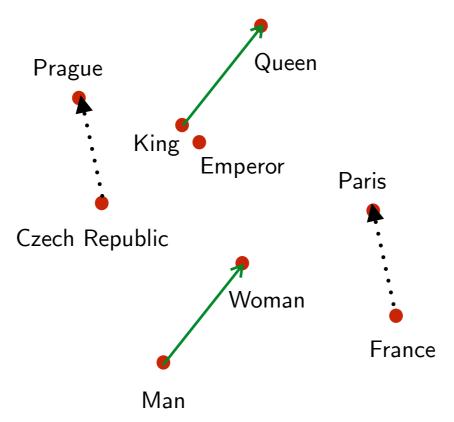

Next week marks the 60th birthday of Townsville resident Jane Smith and plans are under way to see her out of middle age in style! Mrs Smith's friends and family have been organizing the birthday celebrations for several months in order to give her forthcoming dotage the full recognition & deserves.

Straw in Townsville town center will be the venue for the event, and the kitchen staff have been working around the clock to create an exciting menu of soft and easily-digestible dishes for Mrs Smith and her guests to enjoy.

In order to make Mrs Smith feel more comfortable on her big day, guests have been invited to attend

Learned a **representation** of each word x as the embedding $v(x) = V_{x,:} \in \mathbb{R}^d$

- Direction of v(x) appears to capture abstract relations:
 - Semantic:

```
"King" - "Man" + "Woman" pprox "Queen"
"Prague" - "Czech Republic" + "France" pprox "Paris"
"Czech" + "currency" pprox "koruna"
```

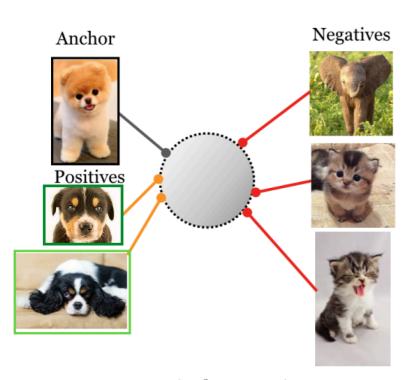

- Syntactic:
 - "quick" "quickly" \approx "slow" "slowly"
- Evaluated on a corpus of relation prediction tasks
- More complex tasks become easier when using such vector representations

Deep Similarity/Metric Learning

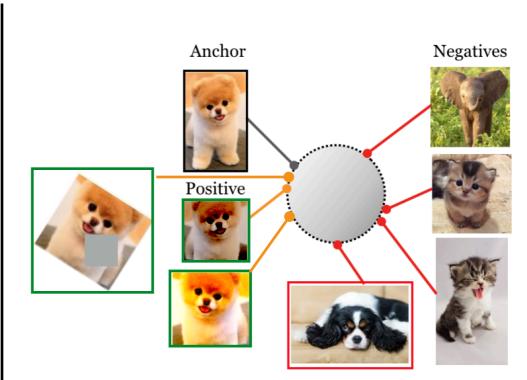

Similarity Learning

10

- ✦ Goals:
 - learn the concept of similarity of two inputs
 - quantify this similarity
- → Supervised learning:
 - Given examples of "similar" and "distinct" pairs learn the function sim(x,y)
 - no reference for the values of sim(x,y)
- → Self-supervised learning:
 - Create "similar" pairs by identity-preserving transforms

Supervised Contrastive

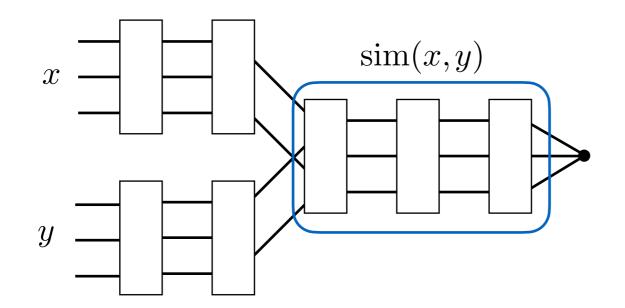

Self Supervised Contrastive

[Khosla et al. (2020) Supervised Contrastive Learning] original graphics edited for visualization

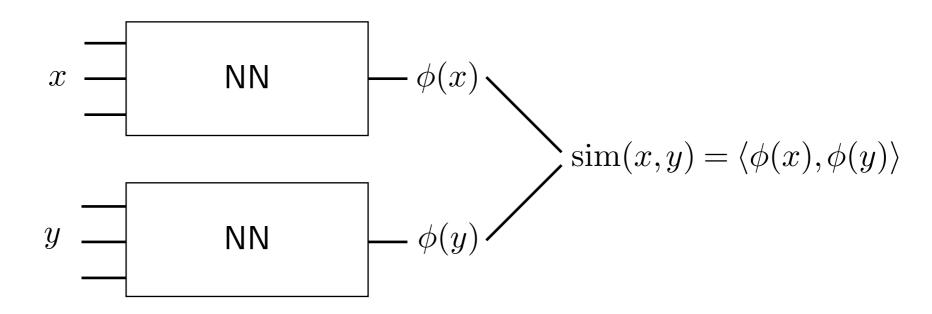

→ Approach 1: generic network with two inputs

first layers extract generic features -- can be shared

→ Approach 2: network creates representations (embeddings / features)

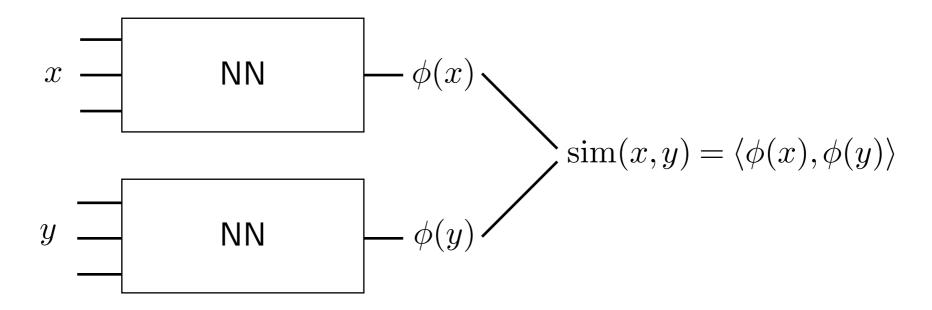

• Inner product: $\langle \phi(x), \phi(y) \rangle$ can approximate any kernel K(x,y)

Similarity Function

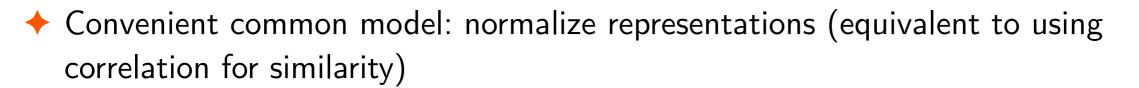

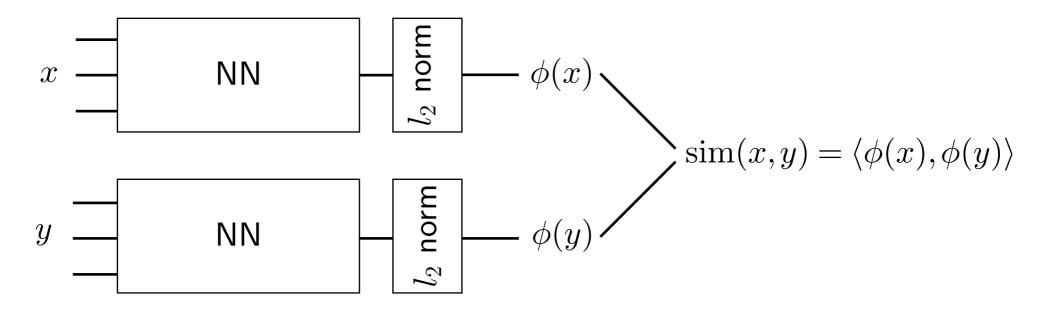

Network creates representations (embeddings / features)

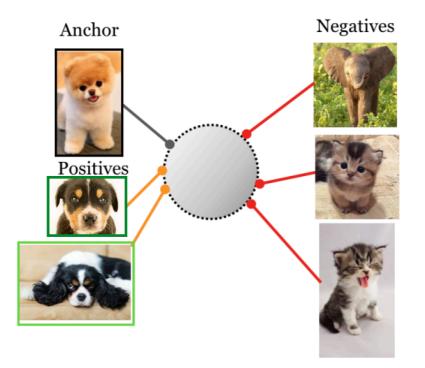

- Inner product: $sim(x,y) = \langle \phi(x), \phi(y) \rangle$ Retrieval: Maximum Inner Product Search (MIPS) is more difficult (no triangle inequality)
- Euclidean: $sim(x,y) = -\|\phi(x) \phi(y)\|^2$ nearest neighbor search (NNS): sub-linear approximate methods
- Correlation: $sim(x,y) = \frac{\langle \phi(x), \phi(y) \rangle}{\|\phi(x)\| \|\phi(y)\|}$ correlation-NNS: sub-linear approximate methods
- All equivalent if $\|\phi(x)\| = 1$ for all x
- There are known mappings to approximate $\langle u,v \rangle$ with $\|P(u)-Q(v)\|^2$ or $\frac{\langle P(u),Q(v) \rangle}{\|P(u)\|\|Q(v)\|}$

Model

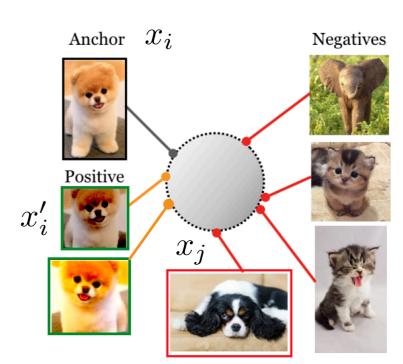

Representations live on a hypersphere

- Training data: $x_1 \dots x_N$
 - Anchor: x_i
 - Positive: $x' = T(x_i)$ random transform
- Model as classification:
 - As many classes as there are instances (data points)
 - Score of instance i: $s_i = \phi(x_i)^T \phi(x')$
 - $p(y=i|x') = \frac{e^{s_i}}{\sum_j e^{s_j}}$
 - Learning formulation: likelihood of classifying corectly

Self Supervised Contrastive

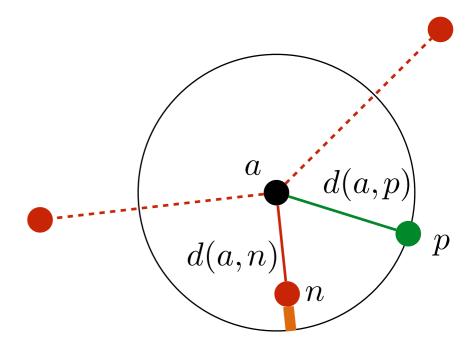

- ullet Large sum in the denominator o common solution is to restrict to a min-batch
- Properties:
 - Ensures instances can be discriminated
 - Enforces invariance to transformations

Dosovitskiy et al. (2014): Discriminative unsupervised feature learning with convolutional neural networks Wu et al. (2018): Unsupervised Feature Learning via Non-Parametric Instance Discrimination Chen et al. (2020): A Simple Framework for Contrastive Learning of Visual Representations Contrastive learning: "contrasting positive pairs against negative pairs"

- Training data: $x_1 \dots x_N$
 - Positive pairs: $x_i \sim x_j$ for $(i,j) \in \mathcal{P}$
 - Negative pairs: $x_i \not\sim x_j$ for $(i,j) \in \mathcal{N}$
 - ullet Example: known class label o similar if same class
- Desired separation property:
 - a anchor (any data point)
 - p positive sample for a
 - n negative
 - let $D_p = d(\mathbf{a}, \mathbf{p})$ and $D_n = d(\mathbf{a}, \mathbf{n})$
 - Want:

$$D_p < D_n \quad \forall p, n$$
$$D_p - D_n < 0$$

- Hinge loss 1: $l = \sum \max(0, D_p D_n)$ $n \in \overline{\mathcal{N}}(a)$
- Hinge loss 2: $l' = \max(0, \max_{n \in \mathcal{N}(a)}(D_p D_n)) = \max_{x \in \mathcal{N}(a) \cup \{p\}}(D_p D_x)$
 - -- hard negative mining

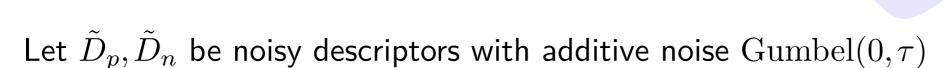

Smooth Triplet Loss = Log Likelihood Classification

- Hinge loss variant 1: $l = \sum_{n \in \mathcal{N}(a)} \max(0, D_p D_n)$
 - Smooth maximum (SoftPlus):

$$Z \sim \text{Logistic}(0, \tau)$$

$$\mathbb{E}[\max(0, x+Z)] = \tau \log(1 + e^{x/\tau})$$

$$\mathbb{E}[\max(0, \tilde{D}_p - \tilde{D}_n)] = \mathbb{E}[\max(0, D_p - D_n + Z)] = \tau \log(1 + e^{(D_p - D_n)/\tau})$$

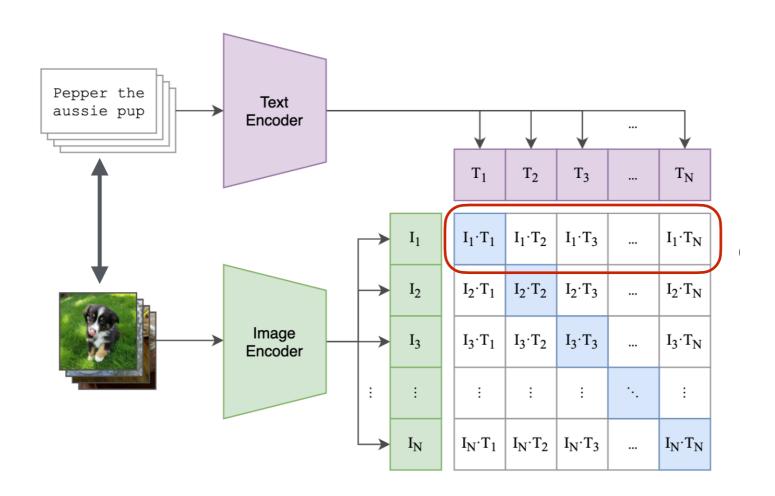

Binary classification of positive vs negative pairs, e.g. [Sohn 2016]

- Hinge loss variant 2: $l' = \max_{x \in \mathcal{N}(a) \cup \{p\}} (D_p D_x)$
 - Let \tilde{D}_p , \tilde{D}_x be noisy descriptors with additive noises $\mathrm{Gumbel}(0,\tau)$
 - $\mathbb{E}[l] = -\tau \log \frac{e^{-D_p/\tau}}{\sum_x e^{-D_x/\tau}}$
 - Log softmax loss back again
 - For the inner product similarity: $\mathbb{E}[l] = -\tau \log \frac{e^{\phi(a)^\mathsf{T} \phi(p)/\tau}}{\sum_x e^{\phi(a)^\mathsf{T} \phi(x)/\tau}}$

Classification loss of predicting the positive out of all candidates

Cross-Modality Representations

CLIP: Connecting Text and Images

- In each batch of image-text pairs with embeddings I_i , T_j :
 - Predict which text corresponds to image i, model: $p_1(j|i) = \frac{e^{\langle I_i, T_j \rangle / \tau}}{\sum_{j'} e^{\langle I_i, T_{j'} \rangle / \tau}}$ Predict which image corresponds to text j, model: $p_1(i|j) = \frac{e^{\langle I_i, T_j \rangle / \tau}}{\sum_{i'} e^{\langle I_{i'}, T_j \rangle / \tau}}$

 - Learning: symmetric cross-entropy loss:

$$-\sum_{i} \left(\log p_1(i|i) + \log p_2(i|i)\right)$$
