Morphology

用 开 开

- Morphology deals with form and structure
- Mathematical morphology is a tool for extracting image components useful in:
 - representation and description of region shape (e.g. boundaries)
 - pre- or post-processing (filtering, thinning, etc.)
- Based on set theory

B: **4**

Definitions: Let A and B be binary images, p and q two pixels with indices [i,j] y [k,l] respectively, and Ω the universal binary image.

Union:

$$A \cup B = \{p | p \in A \lor p \in B\}$$
 Intersection:

 $A \cap B = \{p | p \in A \land p \in B\}$ Complement:

$$\overline{A} = \{p | p \in \Omega \land p \not\in A\}$$
 Difference:

$$A - B = A \cap \overline{B}$$

Translation:

$$A_p = \{a + p | a \in A\}$$

Vectorial sum:

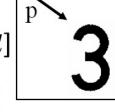

$$p+q = [i+k, j+l]$$

- Vectorial difference:

$$p - q = [i - k, j - l]$$

Reflex:

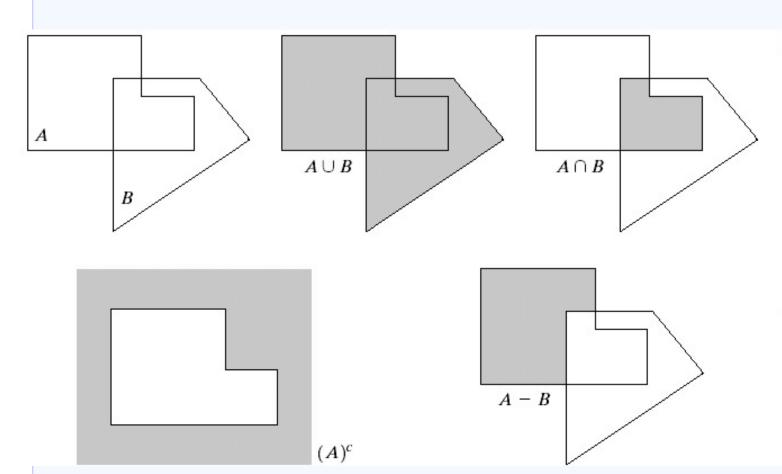

$$A' = \{-p|p \in A\}$$

- Fig. 9.1.

Dilation & Erosion

 The value of the output pixel is the *maximum* value of all the pixels in the input pixel's neighborhood.

- Dilation:

$$A \oplus B = \{x \mid [(\hat{B})_x \cap A] \subseteq A\}$$

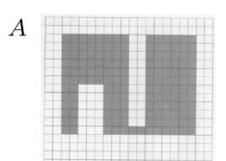

- •B is the structuring element in dilation.
- The value of the output pixel is the *minimum* value of all the pixels in the input pixel's neighborhood.
- Erosion:

$$A \quad B = \{x \mid (B)_x \subseteq A\}$$

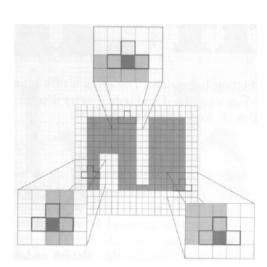

Dilation & Erosion

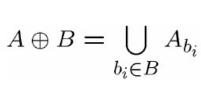

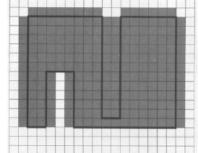

B

 Dilation: union of translations of an image A by each pixel of image B, called structural element:

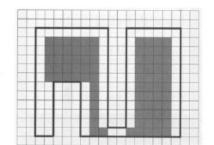

Erosion inverse operation

$$A \ominus B = \{p | B_p \subseteq A\}$$

Morphological Image Processing

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

Opening & Closing

- In essence, dilation expands an image and erosion shrinks it.
- Opening:
 - generally smoothes the contour of an image, breaks isthmuses, eliminates protrusions.
- Closing:
 - smoothes sections of contours, but it generally fuses breaks, holes, gaps, etc.
- Opening of A by structuring element B:

$$A \circ B = (A \ominus B) \oplus B$$

Closing:

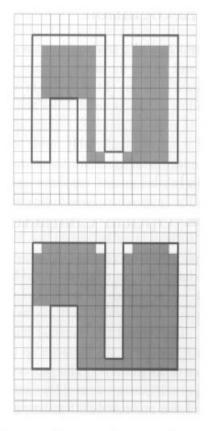

$$A \bullet B = (A \oplus B) \ominus B$$

 Opening: erosion + dilation with the same element

$$A \circ K = (A \ominus K) \oplus K$$

 Eliminates all regions too small to contain the structural element Closing: dilation + erosion with the same element

$$A \bullet K = (A \oplus K) \ominus K$$

 Fills all holes and cavities smaller than the structural element

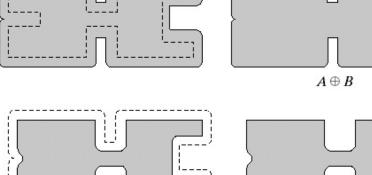

Morphological Image Processing

Thinning

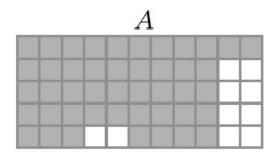

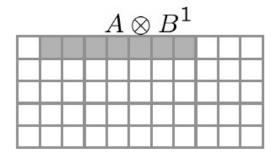

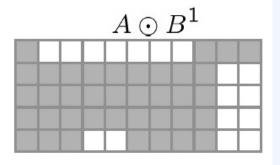

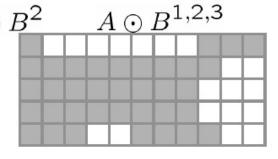

$$A \odot B^i = A - (A \otimes B^i)$$

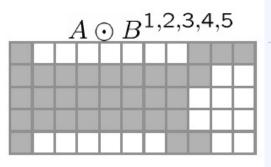

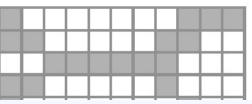

$$A \odot B^{1,2} = (A \odot B^1) \odot B^2$$

$$X_0 = A$$

 $X_k = X_{k-1} \odot B^{\{1,\dots,n\}}$

Post-processing

- -Reduces the width of the ridges to one pixel
- Skeletons, spikes
- -Filling holes, removing small breaks, eliminating bridges between ridges etc.
- cleanskeleton: removespur, linkbreak, removebridge

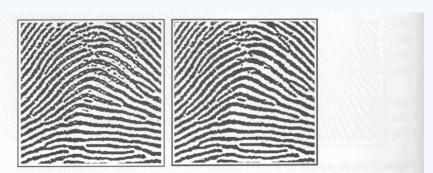

Figure 3.35. The result of eliminating small holes from both the ridges and valleys of the binary image; input image is shown on the left and the output is shown on the right. The filtering is performed by computing the connected components of the image and by removing the components whose area (number of pixels) is smaller than a given threshold.

Poincare Method

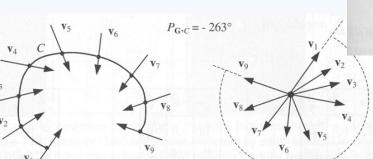

Figure 3.14. The Poincaré index computed over a curve C immersed in a vector field G.

$P_{\mathbf{G},C}(i,j) = \begin{cases} & \\ & \end{cases}$	0°	if $[i, j]$ does not belong to any singular region
	360°	if $[i, j]$ belongs to a whorl type singular region
	180°	if $[i, j]$ belongs to a whorl type singular region if $[i, j]$ belongs to a loop type singular region
	-180°	if $[i, j]$ belongs to a delta type singular region.

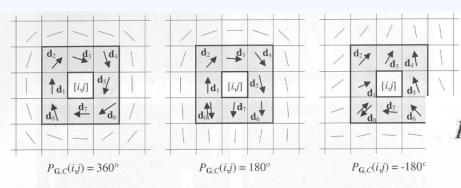

Figure 3.15. Example of computation of the Poincaré index in the 8-neighborhood of points belonging (from the left to the right) to a whorl, loop, and delta singularity, respectively. Note that for the loop and delta examples (center and right), the direction of \mathbf{d}_0 is first chosen upward (to compute the angle between \mathbf{d}_0 and \mathbf{d}_1) and then successively downward (when computing the angle between \mathbf{d}_7 and \mathbf{d}_0).

Gerstner

Poincare Method

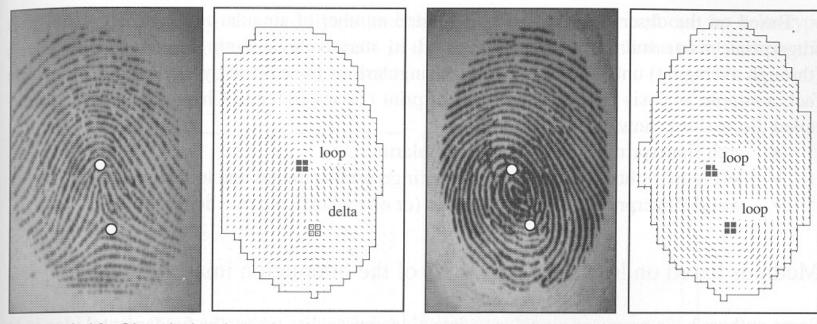

Figure 3.16. Singularity detection by using the Poincaré index method. The elements whose Poincaré index is 180° (loop) or -180° (delta) are enclosed by small boxes. Usually, more than one point (four points in these examples) is found for each singular region: hence, the center of each singular region can be defined as the barycenter of the corresponding points.

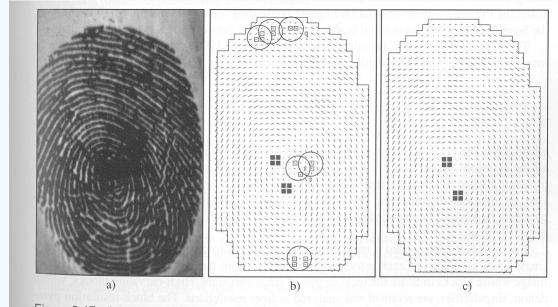

Poincare Method

If we know the type of the fingerprint beforehand, false singularities can be eliminated by iteratively smoothing the image with the help of the following observation:

- Arch fingerprints do not contain singularities
- Left loop, right loop and tented arch fingerprints contain one loop and one delta
- Whorl fingerprints contain two loops and two deltas

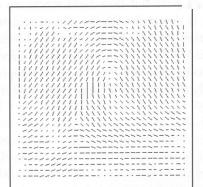

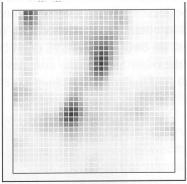

- Methods based on local features
 - Orientation histograms at local level (3x3)
 - Irregularity
 - Fp1 = findsingularitypoint(Fp1);
 - $-d_{ij} = [r_{ij}.\cos 2\theta_{ij}, r_{ij}\sin 2\theta_{ij}]$

$$irregularity(i, j) = 1 - \frac{\left| \sum_{h=-1..1} \sum_{k=-1..1} \mathbf{d}_{i+h \ j+k} \ \right| \left|}{\sum_{h=-1..1} \sum_{k=-1..1} \left| \left| \mathbf{d}_{i+h \ j+k} \ \right| \right|},$$

Partitioning based methods

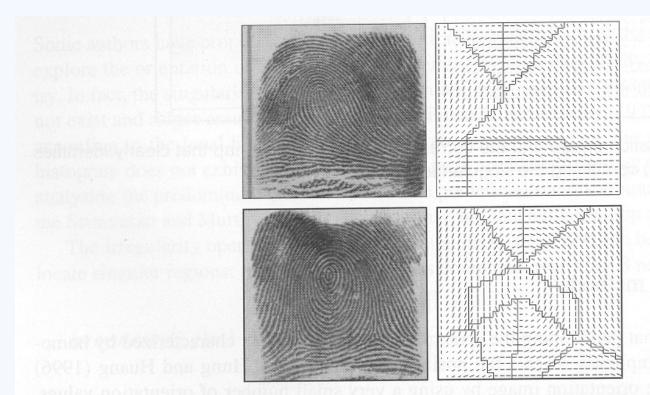

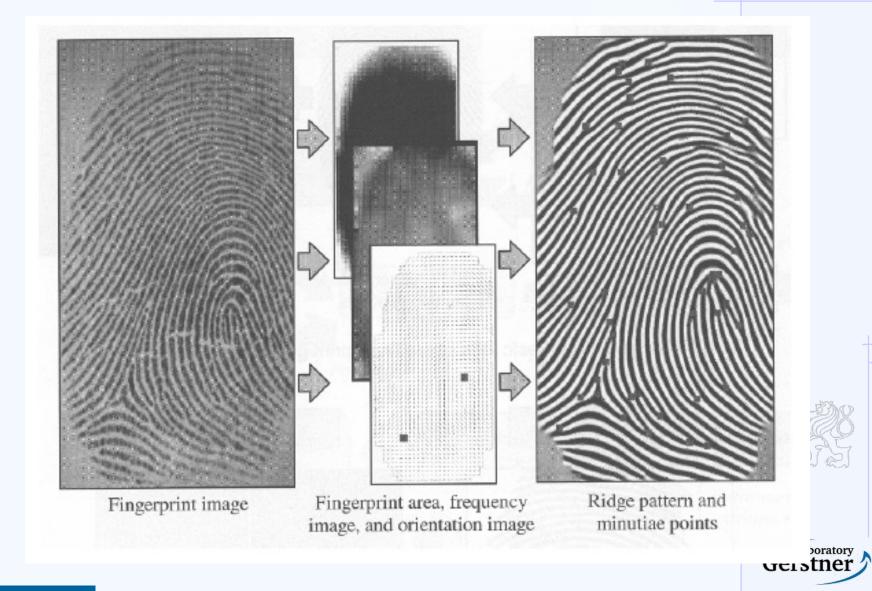

Figure 3.19. Orientation image partitioning with the MASK approach (Cappelli et al., 1999). The intersections between region border lines denote fingerprint singularities. ©IEEE.

Feature Extraction

Feature Extraction Errors

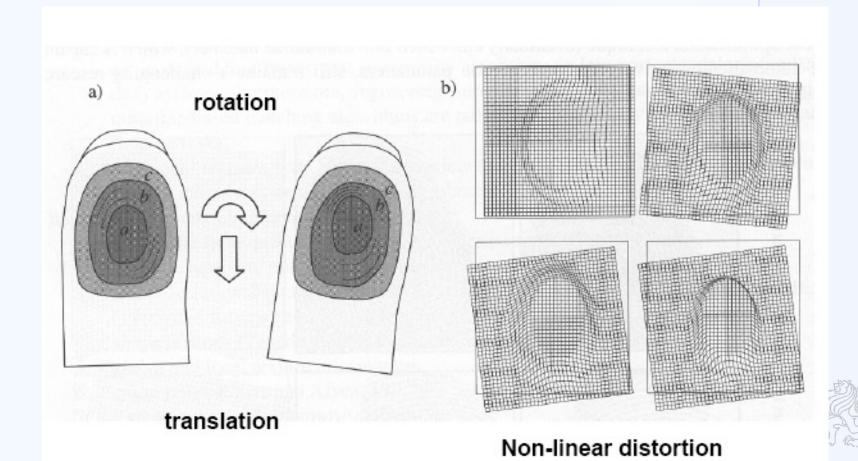

- The feature extraction algorithms are imperfect and often introduce measurement errors
- Errors may be made during any of the feature extraction stages, e.g., estimation of orientation and frequency images, detection of the number, type, and position of the singularities and minutiae, segmentation of the fingerprint area from bacground, etc.
- Aggressive enhancement algorithms may introduce inconsistent biases that perturb the location and orientation of the reported minutiae from their grayscale counterparts
- In low-quality fingerprint images, the minutiae extraction process may introduce a large number of spurious minutiae and may not be able to detect all the true minutiae

Non-linear distortion

Intra-variability

- Matching fingerprint images is an extremely difficult problem, mainly due to the large variability in different impressions of the same finger (intra-variability). The main factors are:
 - Displacement (global translation of the fingerprint area)
 - Rotation
 - Partial overlap
 - Non-linear distortion:
 - the act of sensing maps the three-dimensional shape of a finger onto the two-dimensional surface of the sensor
 - skin elasticity
 - Pressure and skin condition
 - Noise: introduced by the fingerprint sensing system
 - Feature extraction errors

Fingerprint matching

Reference fingerprint

Test fingerprint

- Comes the test- and the reference fingerprint from the same finger?
 the two fingerprints can be translated and rotated relative to each other.
- Minutiae based matching: by direct use of the local structure of the fingerprints extract common minutiae points.

MATCHING: Approaches

用用用

- Correlation-based matching
 - Superimpose images compare pixels
- Minutiae-based matching
 - Classical Technique Most popular
 - Compare extracted minutiae
- Ridge Feature-based matching
 - Compare the structures of the ridges
 - Everything else

Fingerprint Matching

E E E

- Compare two given fingerprints T_rI
 - Return degree of similarity (0->1)
 - Binary Yes/No
- T-> template, acquired during enrollment
- *− I −>* Input
- Either input images, or feature vectors (minutiae) extracted from them
- Pressure and Skin condition
 - Pressure, dryness, disease, sweat, dirt, grease, humidity
- Noise
 - Dirt on the sensor
- Feature Extraction Errors
- Many algorithms match high quality images
- Challenge is in low-quality and partial matches
- 20% of the problems (low quality) at FVC2000 caused 80% of the false non-matches
- Many were correctly identified at FVC2002 though

Correlation-based Techniques

- T and I are images
- Sum of squared Differences

$$- SSD(T,I) = ||T-I||^2 = (T-I)^T(T-I) = ||T||^2 + ||I|||^2 - 2T^TI$$

- Difference between pixels
- $||T||^2 + ||I||^2$ are constant under transformation
- Try to maximize correlation Minimizes difference
 - CC(T,I) = T^TI
 - Can't be used because of displacement / rotation

$-\int (\Delta x, \Delta y, \theta)$

Maximizing Correlation

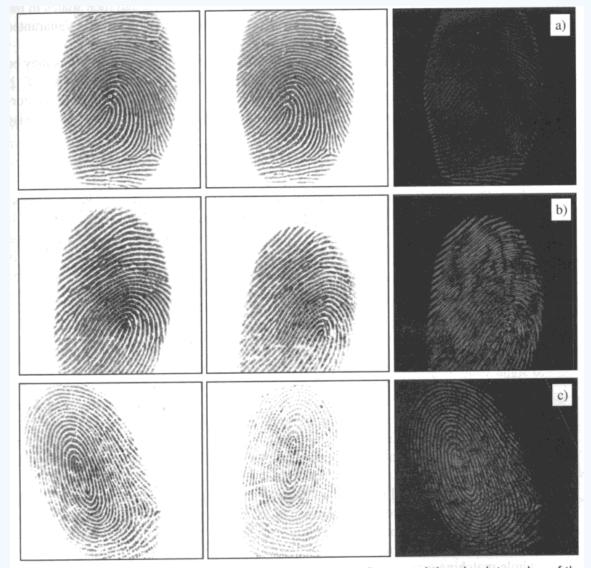

- Transformation of I
- Rotation around the origin by θ
- Translation by x,y
- $S(T,I) = \max CC(T,I^{(\Delta x,\Delta y,\theta)})$
 - Try them all take max

$$S(\mathbf{T}, \mathbf{I}) = \max_{\Delta x, \Delta y, \theta} CC(\mathbf{T}, \mathbf{I}^{(\Delta x, \Delta y, \theta)})$$

Correlation Results

Minutiae-based Methods

田田田

- T, I are feature vectors of minutiae
- Minutiae = (x,y,θ)
- Two minutiae match if
 - Euclidean distance < r₀
 - Difference between angles $< \theta_0$
 - Tolerance Boxes

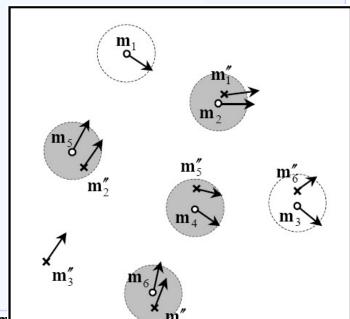

$$- r_0$$

$$-\theta_0$$

$$sd(\mathbf{m}'_{j}, \mathbf{m}_{i}) = \sqrt{(x'_{j} - x_{i})^{2} + (y'_{j} - y_{i})^{2}} \leq r_{0,} \text{ and}$$
$$dd(\mathbf{m}'_{j}, \mathbf{m}_{i}) = min(|\theta'_{j} - \theta_{i}|, 360^{\circ} - |\theta'_{j} - \theta_{i}|) \leq \theta_{0}.$$

$$\mathbf{m} = \{x, y, \theta\}$$

$$\begin{split} \mathbf{T} &= \big\{ \mathbf{m}_1, \mathbf{m}_2, ... \mathbf{m}_m \big\}, \quad \mathbf{m}_i &= \big\{ x_i, y_i, \theta_i \big\}, \quad i = 1...m \\ \mathbf{I} &= \big\{ \mathbf{m}_1', \mathbf{m}_2', ... \mathbf{m}_n' \big\}, \quad \mathbf{m}_j' &= \big\{ x_j', y_j', \theta_j' \big\}, \quad j = 1...n, \end{split}$$

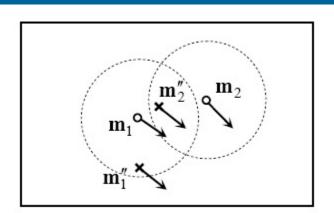

Formulation

用用

- $M''_{j} = map(m'_{j})$
 - Map applies a geometrical transformation
- mm(m"_i, m_i) returns 1 if they match
- Matching can be formulated as

$$\underset{\Delta x, \Delta y, \theta, P}{\text{maximize}} \sum_{i=1}^{m} mm \Big(map_{\Delta x, \Delta y, \theta} \Big(\mathbf{m}'_{P(i)} \Big), \mathbf{m}_{i} \Big)$$

P is an unknown function which pairs the minutiae

Which minutiae in I corresponds to which in T: allign2

$$map_{\Delta x, \Delta y, \theta} \left(\mathbf{m}'_j = \left\{ x'_j, y'_j, \theta'_j \right\} \right) = \mathbf{m}''_j = \left\{ x''_j, y''_j, \theta'_j + \theta \right\}, \text{ where}$$

$$\begin{bmatrix} x_j'' \\ y_j'' \end{bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} x_j' \\ y_j' \end{bmatrix} + \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}.$$

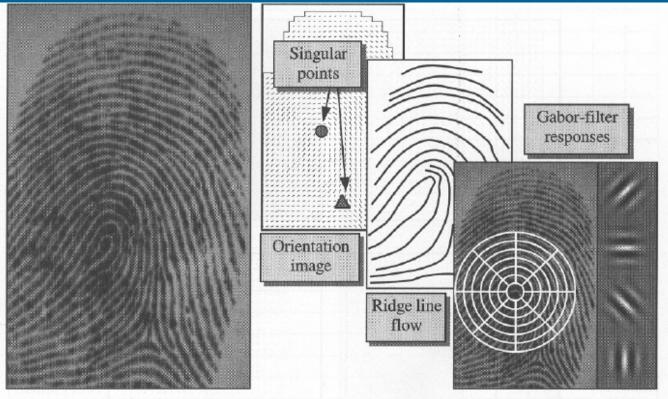

$$mm(\mathbf{m}_{j}'', \mathbf{m}_{i}) = \begin{cases} 1 & sd(\mathbf{m}_{j}'', \mathbf{m}_{i}) \leq r_{0} \text{ and } dd(\mathbf{m}_{j}'', \mathbf{m}_{i}) \leq \theta_{0} \\ 0 & \text{otherwise.} \end{cases}$$

Ridge feature based matching

Most frequently used features for fingerprint matching:

- -Orientation image
- -Singular points (loop and delta)
- -Ridge line flow
- -Gabor filter responses

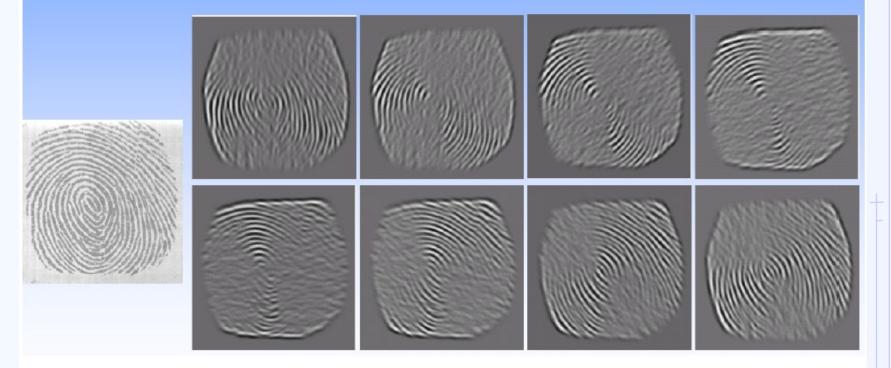

Gabor filters

An input fingerprint image is filtered using 8 Gabor filters all having the same frequency but different orientations (0°, 22.5°, 45°, 67.5°, 90°, 112.5°, 135°, 157.5°)

Local texture analysis

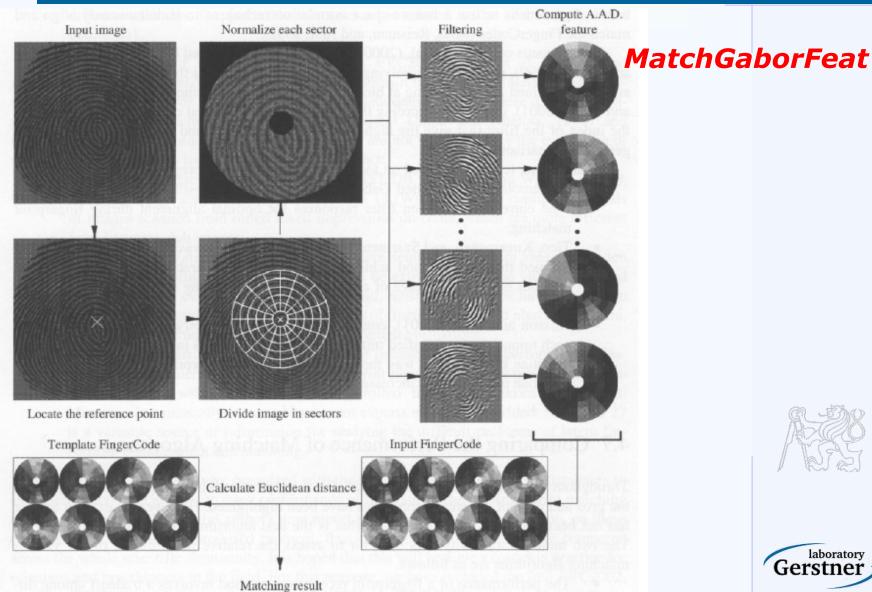

- The fingerprint area of interest is tesselated with respect to the core point
- The local texture information in each sector is decomposed into separate channels by using a Gabor filterbank
- Feature vector:
 - 80 cells (5 bands and 16 sectors)
 - Filterbank of 8 Gabor filters (8 orientations, 1 scale =1/10 for 500 dpi fingerprint images)
 - Each fingerprint is represented by a 80x8 = 640 fixed-size feature vector, called the FingerCode
- Computation of average absolute deviation (AAD)

Finger code approach

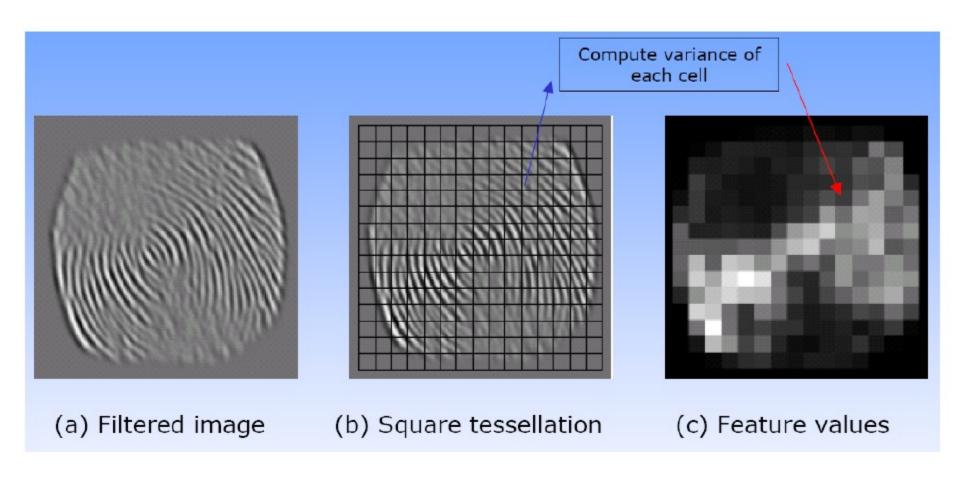

Texture based representation

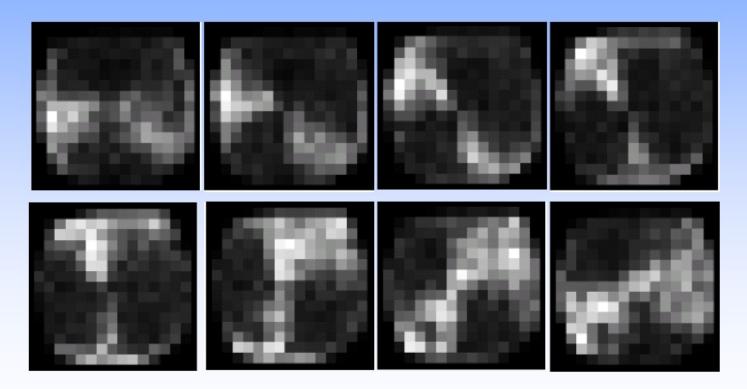

Ridge feature map

 The filtered images are examined using a square tessellation and the variance of pixel intensities in every cell is used as a feature value

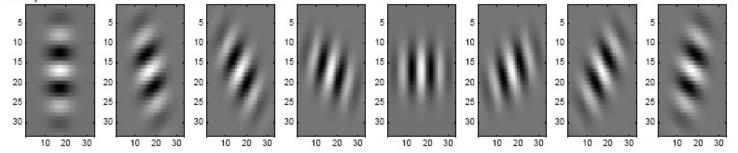

The ridge feature map is a fixed-length feature vector
