Parallel Computing using GPU

Part I

Part 1 – Introduction to Parallel Programming

Parallel Programming

- The idea of parallel programming comes from the 60s with the first multi-program and pseudo-parallel systems
- Parallelism
 - Hardware based true hardware parallelism of multiprocessor systems
 - Software based pseudo-parallelism
- Pseudo-parallelism A program with parallel constructions may run in pseudo-parallel environment on single or multi-processor systems

Motivation Why to Deal with Parallel Programming

- Increase computational power
 - Having multi-processor system we can solve the computational problem faster
- Efficient usage of the computational power
 - Even a running program may wait for data
 - E.g., a usual program with user-interaction typically waits for the user input
- Simultaneous processing of many requests
 - Handling requests from individual clients in client/server architecture

Process – Executed Program

- Process is an executed program running in a dedicated memory space
- Process is an entity of the Operating System (OS) that is scheduled for an independent execution
- Process is usually in one of three basic states:
 - Executing currently running on the processor (CPU)
 - Blocked waiting for the periphery
 - Waiting waiting for the processor
- A process is identified in OS by an identifier, e.g., PID

Semaphores

Scheduler of the OS manage running processes to be allocated to the available processors

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

Process States

Data become ready External event Ready to run the process processes Transition to the head queue with Blocked ready processes Scheduler picks processes another process Running System call that cannot be handled immediatelly process Process asked for termination System call that can be performed immediatelly

Multi-processor Systems

- Multi-processor systems allow true parallelism
- It is necessary to synchronize processors and support data communication
 - Resources for activity synchronization
 - Resources for communication between processors (processes)

Possible Architectures for Parallel Executions

- Control of individual instructions
 - SIMD Single-Instruction, Multiple-Data same instructions are simultaneously performed on different data.
 - "Processors" are identical and run synchronously
 - E.g., "Vectorization" such as MMX, SSE, 3Dnow!, and AVX, etc.
 - MIMD Multiple-Instruction, Multiple-Data processors run independently and asynchronously
- Memory Control Access
 - Systems with shared memory central shared memory

E.g., multi-core CPUs

Systems with distributed memory – each processor has its memory

E.g., computational grids

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

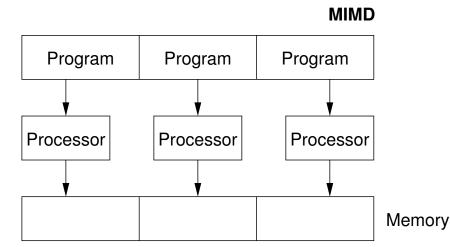

10 / 63

Jan Faigl, 2017

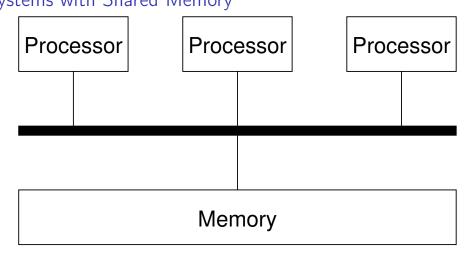

BE5B99CPL - Lecture 07: Parallel Programming

Introduction

MIMD – Multiple-Instruction, Multiple-Data

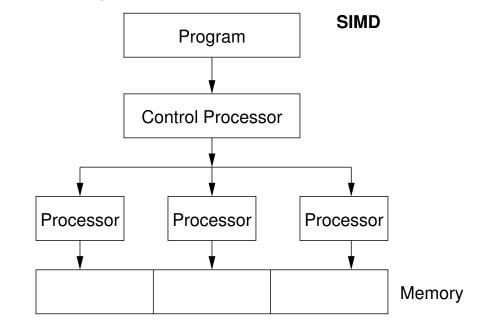

Systems with Shared Memory

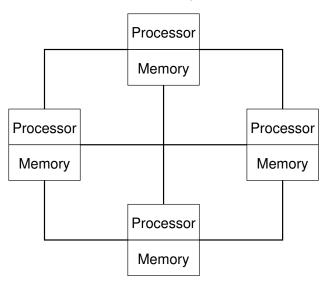

- Processors communicate using shared memory space
- Processors may also synchronize their activities, i.e., grant exclusive access to the memory

SIMD - Single-Instruction, Multiple-Data

Shared Memory

Systems with Distributive Memory

- There is not a problem with exclusive access to the memory
- It is necessary to address communication between the processors

Jan Faigl, 2017 14 / 63 BE5B99CPL - Lecture 07: Parallel Programming

Parallel Processing and Programming Languages

- Regarding parallel processing, programming languages can be divided into
 - Without explicit support for parallelism possible mechanisms of parallel processing
 - 1. Parallel processing is realized by compiler and operating system
 - 2. Parallel constructions are explicitly marked for the compiler
 - 3. Parallel processing is performed by OS system calls
 - With explicit support for parallelism

The Role of the Operating System (OS)

- OS provides hardware abstraction layer encapsulates HW and separates the user from the particular hardware architecture (true/pseudo parallelism)
- OS is responsible for processes synchronization
- OS provides user interfaces (system calls):
 - To create and destroy processes
 - To manage processes and processors
 - To schedule processors on available processors
 - To control access to shared memory
 - Mechanisms for inter-process communication (IPC)
 - Mechanisms for processes synchronization

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

Example of Parallel Processing Realized by Compiler 1/2

```
Example - Array Multiplication
```

```
#include <stdlib.h>
    #define SIZE 30000000
   int main(int argc, char *argv[])
        int *in1 = (int*)malloc(SIZE*sizeof(int));
        int *in2 = (int*)malloc(SIZE*sizeof(int));
        int *out = (int*)malloc(SIZE*sizeof(int));
        for (i = 0; i < SIZE; ++i) {</pre>
11
            in1[i] = i;
12
            in2[i] = 2 * i;
13
14
        for (i = 0; i < SIZE; ++i) {</pre>
15
            \operatorname{out}[i] = \operatorname{in1}[i] * \operatorname{in2}[i]:
16
            \operatorname{out}[i] = \operatorname{out}[i] - (\operatorname{in1}[i] + \operatorname{in2}[i]);
17
18
        return 0;
19
```

Example of Parallel Processing Realized by Compiler 2/2

```
Example 1
                    Example 2
icc compute.c
                  icc -msse compute.c; time ./a.out
time ./a.out
                    compute.c(8): (col. 2) remark: LOOP WAS
                         VECTORIZED
real 0m0.562s

Example – Open MP – Matrix Multiplication 2/2

■ Comparison of matrix multiplication with 1000×1000 matrices using OpenMP on iCore5 (2 cores with HT)

```
gcc -std=c99 -02 -o demo-omp demo-omp-matrix.c -fopenmp
    ./demo-omp 1000
   Size of matrices 1000 x 1000 naive
           multiplication with O(n^3)
   c1 == c2: 1
   Multiplication single core 9.33 sec
   Multiplication multi-core 4.73 sec
   export OMP_NUM_THREADS=2
9
    ./demo-omp 1000
10
   Size of matrices 1000 x 1000 naive
11
            multiplication with O(n^3)
12
   c1 == c2: 1
   Multiplication single core 9.48 sec
   Multiplication multi-core 6.23 sec
```

Parallel Processing

lec07/demo-omp-matrix.c

Example – Open MP – Matrix Multiplication 1/2

Parallel Processing

 Open Multi-Processing (OpenMP) - application programming interface for multi-platform shared memory multiprocessing

Messages

Shared Memory

http://www.openmp.org

- We can instruct compiler by macros for parallel constructions
 - Example of parallelization over the outside loop for i variable

```
void multiply(int n, int a[n][n], int b[n][n], int c[n][n])
2 {
3
      int i;
   #pragma omp parallel private(i)
   #pragma omp for schedule (dynamic, 1)
      for (i = 0; i < n; ++i) {
          for (int j = 0; j < n; ++j) {
             c[i][i] = 0;
            for (int k = 0; k < n; ++k) {
                c[i][j] += a[i][k] * b[k][j];
10
11
12
13
                                               lec07/demo-omp-matrix.c
   }
14
```

Squared matrices of the same dimensions are used for simplicity.

Jan Faigl, 2017

Introduction

Languages with Explicit Support for Parallelism

- It has support for creation of new processes
 - Running process creates a copy of itself
 - Both processes execute the identical code (copied)
 - The parent process and child process are distinguished by the process identifier (PID)
 - The code segment is explicitly linked with the new process
- Regardless how new process is created the most important is
 - Does the parent process stops its execution till the end of the child
 - Is the memory shared by the child and parent processes
- Granularity of the processes parallelism ranging from the level of the instructions to the parallelism of programs

Messages Shared Memory Semaphores Messages Shared Memory

Parallelism – Statement Level

Example – parbegin-parend block parbegin *S*₁; *S*₂; parend

- Statement S_1 are S_n executed in parallel
- **Execution** of the main program is interrupted until all statements S_1 to S_n are terminated
- Statement S_1 are S_n executed in parallel

Example – doparallel

```
for i = 1 to n doparalel {
   for j = 1 to n do {
      c[i,j] = 0;
      for k = 1 to n do {
         c[i,j] = c[i,j] + a[i,k]*b[k,j];
```

Parallel execution of the outer loop over all i.

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

23 / 63

Parallelism – Program (Process) Level

- A new process can be only a whole program
- A new program is created by a system call, which creates a complete copy of itself including all variable and data at the moment of the call

Example - Creating a copy of the process by fork system call

```
if (fork() == 0) {
   /* code executed by the child process */
   /* code executed by the parent process */
```

E.g., fork() in C

Parallelism – Procedure Level

A procedure is coupled with the execution process

```
procedure P:
PID x_{pid} = newprocess(P);
killprocess(x_{pid});
```

- P is a procedure and x_{pid} is a process identifier
- Assignment of the procedure/function to the process at the declaration

```
PID x_{pid} process(P).
```

Parallel Processing

- The process is created at the creation of the variable x
- The process is terminated at the end of x or sooner

E.g., Threads (pthreads) in C

Jan Faigl, 2017 BE5B99CPL - Lecture 07: Parallel Programming

lec07/demo-fork.c

Semaphores

Example - fork()

```
1 #define NUMPROCS 4
    for (int i = 0; i < NUMPROCS; ++i) {</pre>
       pid_t pid = fork();
       if (pid == 0) {
          compute(i, n);
          exit(0);
       } else {
          printf("Child %d created\n", pid);
 9
10
    printf("All processes created\n");
12 for (int i = 0; i < NUMPROCS; ++i) {</pre>
       pid_t pid = wait(&r);
       printf("Wait for pid %d return: %d\n",
         pid, r);
15 }
    void compute(int myid, int n)
17
       printf("Process myid %d start
18
             computing\n", myid);
19
20
       printf("Process myid %d
             finished\n", myid);
```

```
clang demo-fork.c && ./a.out
                  Child 2049 created
                  Process myid 0 start computing
                  Child 2050 created
                  Process myid 1 start computing
                  Process myid 2 start computing
                  Child 2051 created
                  Child 2052 created
                  Process myid 3 start computing
                  All processes created
                  Process myid 1 finished
                  Process myid 0 finished
                  Wait for pid 2050 return: 0
                  Process myid 3 finished
                  Process myid 2 finished
                  Wait for pid 2049 return: 0
                  Wait for pid 2051 return: 0
                  Wait for pid 2052 return: 0
BE5B99CPL - Lecture 07: Parallel Programming

```

Jan Faigl, 2017

Semaphore

- E.W.Dijkstra semaphore is a mechanism to synchronize parallel processes with shared memory
- Semaphore is an integer variable with the following operations
 - InitSem initialization
 - Wait $\begin{cases} S > 0 S = S 1 \\ \text{otherwise suspend execution of the calling process} \end{cases}$
 - Signal $\begin{cases} \text{awake a waiting process if such process exists} \\ \text{otherwise} S = S + 1 \end{cases}$
- Semaphores can be used to control access to shared resources
 - S < 0 shared resource is in use; the process asks for the access to the resources and waits for its release
 - \blacksquare S > 0 shared resource is available; the process releases the resource

The value of the semaphore can represent the number of available resources

Semaphores Implementation

Operations with a semaphore must be atomic

Semaphores

The processor cannot be interrupted during execution of the operation

Shared Memory

Parallel Computing using GPU

- Machine instruction TestAndSet reads and stores a content of the addressed memory space and set the memory to a non-zero value
- During execution of the TestAndSet instructions the processor holds the system bus and access to the memory is not allowed for any other processor

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

BE5B99CPL - Lecture 07: Parallel Programming

Jan Faigl, 2017

Usage of Semaphores

- Semaphores can be utilized for defining critical sections
- Critical section is a part of the program where exclusive access to the shared memory (resources) must be guaranteed

Example of critical section protected by a semaphore InitSem(S,1); Wait(S): /* Code of the critical section */ Signal(S);

Synchronization of the processes using semaphores

Example of synchronization of processes

```
/* process p */
                                /* process q */
InitSem(S,0)
                                Signal(S);
Wait(S); ...
                                exit();
exit();
```

Process p waits for termination of the process q

Example – Semaphore 1/4 (System Calls)

Semaphore is an entity of the Operating System (OS)

```
#include <sys/types.h>
#include <sys/ipc.h>
3 #include <sys/sem.h>
   /* create or get existing set of semphores */
6 int semget(key_t key, int nsems, int flag);
  /* atomic array of operations on a set of semphores */
  int semop(int semid, struct sembuf *array, size_t nops);
   /* control operations on a st of semaphores */
int semctl(int semid, int semnum, int cmd, ...);
```

Semaphores Semaphores

Example – Semaphore 2/4 (Synchronization Protocol)

- Example when the main (master) process waits for two other processes (slaves) become ready
 - 1. Master process suspend the execution and waits for two other processes *slaves* become ready
 - 2. Slave processes then wait to be released by the master process
- Proposed synchronization "protocol"
 - Define our way to synchronize the processes using the system semaphores
 - Slave process increments semaphore by 1
 - Slave process waits for the semaphore becomes 0 and then it is
 - Master process waits for two slave processes and decrements the semaphore about 2
 - It must also ensure the semaphore value is not 0; otherwise slaves would be terminated prematurely
 - We need to use the atomic operations with the semaphore

```
lec07/sem-master.c lec07/sem-slave.c
```

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

32 / 63

Jan Faigl, 2017

Shared Memory Parallel Computing using GPU

Example – Semaphore 4/4 (Slave Process)

```
int main(int argc, char* argv[])
2
      struct sembuf sem;
      int id = semget(1000, 1, 0);
      int r;
5
      if (id != -1) {
          sem.sem_num = 0; // add the slave
7
          sem.sem_op = 1; // to the "pool" of resources
8
          sem.sem_flg = 0;
9
          printf("Increase semafore value (add resource)\n");
10
11
          r = semop(id, \&sem, 1);
12
          sem.sem_op = 0;
          printf("Semaphore value is %d\n", semctl(id, 0, GETVAL, 0));
13
          printf("Wait for semaphore value 0\n");
14
         r = semop(id, \&sem, 1);
15
          printf("Done\n");
16
17
      return 0;
18
19
                                                    lec07/sem-master.c
```

The IPC entities can be listed by ipcs clang sem-master.c -o sem-master clang sem-slave.c -o sem-slave

Example – Semaphore 3/4 (Master Process)

```
int main(int argc, char* argv[])
3
      struct sembuf sem[2]; // structure for semaphore atomic operations
      int id = semget(1000, 1, IPC_CREAT | 0666); // create semaphore
      if (id != -1) {
         int r = semctl(id, 0, SETVAL, 0) == 0;
         sem[0].sem_num = 0; // operation to acquire semaphore
         sem[0].sem_op = -2; // once its value would be >= 2
 9
         sem[0].sem_flg = 0; // representing that two slaves are ready
11
         sem[1].sem_num = 0; // the next operation in the atomic set
12
         sem[1].sem_op = 2; // of operations increases the value of
13
         sem[1].sem_flg = 0; // the semaphore about 2
14
         printf("Wait for semvalue >= 2\n");
16
         r = semop(id, sem, 2); // perform all operations atomically
17
         printf("Press ENTER to set semaphore to 0\n");
19
         getchar();
         r = semctl(id, 0, SETVAL, 0) == 0; // set the value of semaphore
20
         r = semctl(id, 0, IPC_RMID, 0) == 0; // remove the semaphore
21
22
      return 0;
                                                  lec07/sem-master.c
24
```

Shared Memory Parallel Computing using GPU

Introduction Parallel Processing Semaphores Messages Shared Memory Parallel Computing using GPU

BE5B99CPL - Lecture 07: Parallel Programming

Issues with Semaphores

- The main issues are arising from a wrong usage
- Typical mistakes are:
 - Wrongly identified a critical section
 - Process may block by multiple calls of Wait(S).
 - E.g., the deadlock issues may arise from situations like

Example – Deadlock

```
/* process 1*/
                                /* process 2*/
Wait(S1);
                                Wait(S2);
Wait(S2);
                                Wait(S1);
Signal(S2);
                                Signal(S1);
Signal(S1);
                                Signal(S2);
```

Semaphores Messages Shared Memory Semaphores Messages Shared Memory

Sensing Messages and Queues of Messages

- Processes can communicate using messages send/received to/from system messages queues
- Queues are entities of the OS with defined system calls

Example of System Calls

```
#include <sys/types.h>
   #include <sys/ipc.h>
   #include <sys/msg.h>
   /*Create a new message queue*/
5
   int msgget(key_t key, int msgflg);
6
   /* Send a message to the queue -- block/non-block (IPC_NOWAIT) */
   int msgsnd(int msqid, const void *msgp, size_t msgsz, int msgflg);
10
   /* Receive message from the queue -- block/non-block (IPC_NOWAIT) */
11
12
   int msgrcv(int msqid, void *msgp, size_t msgsz, long msgtyp, int msgflg);
13
   /* Control operations (e.g., destroy) the message queue */
   int msgctl(int msqid, int cmd, struct msqid_ds *buf)
                 Another message passing system can be implemented by a user library,
```

e.g., using network communication

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

Parallel Computing using GPU

37 / 63

Introduction

Example – Messages Passing 2/4 (Master)

Example of master process 2/2

```
msg.mtype = 3; //type must be > 0
1
          printf("Wait for other process \n");
2
         r = msgrcv(id, &msg, SIZE, 3, 0);
3
          printf("Press ENTER to send work\n");
          getchar();
5
6
          strcpy(msg.mtext, "Do work");
7
          msg.mtype = 4; //work msg is type 4
         r = msgsnd(id, &msg, sizeof(msg.mtext), 0);
8
          fprintf(stderr, "msgsnd r:%d\n",r);
9
          printf("Wait for receive work results\n",r);
10
11
          msg.mtype = 5;
          r = msgrcv(id, &msg, sizeof(msg.mtext), 5, 0);
12
          printf("Received message:%s\n", msg.mtext);
13
          printf("Press ENTER to send exit msg\n");
14
          getchar();
15
          msg.mtype = EXIT_MSG; //I choose type 10 as exit msg
16
          r = msgsnd(id, \&msg, 0, 0);
17
18
19
       return 0;
20
                                                    lec07/msg-master.c
```

Example – Messages Passing 1/4 (Synchronization, Master)

- Two processes are synchronized using messages
 - 1. The master process waits for the message from the slave process
 - 2. The master process informs slave to solve the task
 - 3. The slave process informs master about the solution
 - 4. The master processes sends message about termination

Example of master process 1/2

```
struct msgbuf {
      long mtype;
       char mtext[SIZE];
   };
   int main(int argc, char *argv[])
      struct msgbuf msg;
      int id = msgget(KEY, IPC_CREAT | 0666);
10
      int r;
      if (id != -1) {
11
```

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

Parallel Processing Semaphores Messages Shared Memory

Example – Messages Passing 3/4 (Slave)

```
int main(int argc, char *argv[])
2
      msg.mtype = 3;
      printf("Inform main process\n");
      strcpy(msg.mtext, "I'm here, ready to work");

Messages Shared Memory Parallel Computing using GPU

Example – Shared Memory 1/4 (Write)

Write a line read from stdin to the shared memory

```
#include <sys/types.h>
   #include <sys/ipc.h>
   #include <sys/shm.h>
   #include <stdio.h>
   #define SIZE 512
   int main(int argc, char *argv[])
9
   {
      char *buf;
10
      int id;
11
      if ((id = shmget(1000, SIZE, IPC_CREAT | 0666)) != -1)
12
         if ( (buf = (char*)shmat(id, 0, 0)) ) {
13
             fgets(buf, SIZE, stdin);
14
             shmdt(buf);
15
         }
16
17
      return 0;
18
19 }
                                                lec07/shm-write.c
```

Shared Memory

Labeled part of the memory accessible from different processes

Messages

Shared Memory

Semaphores

OS service provided by system calls

Example of System Calls

```
/* obtain a shared memory identifier */
int shmget(key_t key, size_t size, int flag);
/* detach shared memory */
void* shmat(int shmid, const void *addr, int flag);
/* detach shared memory */
int shmdt(const void *addr);
/* shared memory control */
int shmctl(int shmid, int cmd, struct shmid_ds *buf);
```

- OS manages information about usage of the shared memory
- OS also manages permissions and access rights

oduction Parallel Processing Semaphores Messages Shared Memory Parallel Computing using

Massive parallelism using graphics cards

- Image rendering performed pixel-by-pixel can be easily parallelized
- Graphics Processing Units (GPU) has similar (or even higher) degree of integration with the main processors (CPU)
- They have huge number of parallel processors

E.g., GeForce GTX 1060 ∼ 1280 cores

- The computational power can also be used in another applications
 - Processing stream of data (SIMD instructions processors).
 - GPGPU General Purpose computation on GPU http://www.gpgpu.org
 - OpenCL (Open Computing Language) GPGPU abstract interface
 - CUDA Parallel programming interface for NVIDIA graphics cards http://www.nvidia.com/object/cuda_home.html

Example - Shared Memory 4/4 (Status)

• A list of accesses to the shared memory using ipcs command

```
after creating shared memory segment and before writing the text
         65539
                       1000 --rw-rw-rw-
                                            jf

```

Computational Power (2008)

Parallel Processing

What is the reported processor computational power?

Semaphores

Graphics (stream) processors

```
CSX700 96 GigaFLOPs
Cell 102 GigaFLOPs
GeForce 8800 GTX 518 GigaFLOPs
Radeon HD 4670 480 GigaFLOPs
```

Peak catalogue values

Main processors :

```
Phenom X4 9950 (@2.6 GHz)

Core 2 Duo E8600 (@3.3 GHz)

Cure 2 Quad QX9650 (@3.3 GHz)

Cure 2 Quad QX9650 (@3.3 GHz)

Core i7 970 (@3.2 GHz)

21 GigaFLOPs
22 GigaFLOPs
35 GigaFLOPs
42 GigaFLOPs
```

Test linpack 32-bit

Is the reported power really achievable?

(float vs double)

How about other indicators

E.g., computational power / power consumption

CSX700 has typical power consumption around 9W

Shared Memory Parallel Computing using GPU Shared Memory Parallel Computing using GPU

CUDA

- NVIDIA Compute Unified Device Architecture.
- Extension of the C to access to the parallel computational units of the GPU
- Computation (kernel) is executed by the GPU
- Kernel is performed in parallel using available computational units
- Host Main processor (process)
- Device GPU
- Data must be in the memory accessible by the GPU

Host memory → Device memory

■ The result (of the computation) is stored in the GPU memory

Host memory ← *Device* memory

51 / 63 Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

Blocks may not be necessarily computed in parallel; based on the

available number of parallel units, particular blocks can be computed

52 / 63

Jan Faigl, 2017

BE5B99CPL - Lecture 07: Parallel Programming

CUDA - Computational Model

E.g., a part of the matrix multiplication

Blocks are organized into the grid

seauentially

Kernel (computation) is divided into blocks

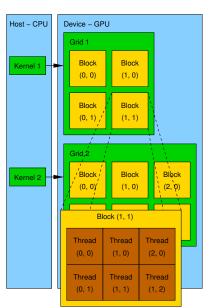

Each block consists of computational threads

Each block represent a parallel computation of the part of the result

Parallel computations are synchronization within the block

Scalability is realized by dividing the computation into blocks

CUDA - Grid, Blocks, Threads, and Memory Access

- Block (0, 0) Shared Memory Registers
- Access time to the memory
- Collisions for simultaneous access of several threads

CUDA – Example – Matrix Multiplication 1/8

- NVIDIA CUDA SDK Version 2.0, matrixMul
- Simple matrix multiplication
 - $\mathbf{C} = \mathbf{A} \cdot \mathbf{B}$
 - Matrices have identical dimensions $n \times n$
 - where *n* is the multiple of the block size
- Comparison
 - naïve implementation in C (3× for loop),
 - naïve implementation in C with matrix transpose
 - CUDA implementation
- Hardware
 - CPU Intel Core 2 Duo @ 3 GHz. 4 GB RAM.
 - GPU NVIDIA G84 (GeForce 8600 GT), 512 MB RAM.

CUDA – Example – Matrix Multiplication 2/8

Naïve implementation

```
void simple_multiply(const int n,
         const float *A, const float *B, float *C)
2
3
     for (int i = 0; i < n; ++i) {
       for (int j = 0; j < n; ++j) {
         float prod = 0;
6
         for (int k = 0; k < n; ++k) {
7
           prod += A[i * n + k] * B[k * n + j];
8
9
         C[i * n + j] = prod;
10
11
12
13
```
