# Robotic Paradigms and Control Architectures

Jan Faigl

Department of Computer Science Faculty of Electrical Engineering Czech Technical University in Prague

Lecture 02

B4M36UIR - Artificial Intelligence in Robotics

Robotic Paradigms

Robotic paradigms define relationship between the robotics primitives: Sense, Plan, and Act.

Overview of the Lecture

■ Part 1 - Robotic Paradigms and Control Architectures

Robotics Paradigms

· Hierarchical Paradigm

Example of Collision Avoidance

Reactive Paradigm

Hybrid Paradigm

Robot Control

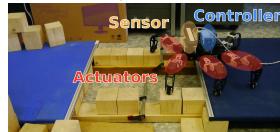

Hierarchical Paradigm

Part I

Part 1 – Robotic Paradigms and Control Architectures

A "world model" can also be an a priori available, e.g., prior map.

A robot perceives an environment using sensors to control its actuators

- The main parts of the robot corresponding to the primitives of robotics: Sense, Plan, and Act.
- The primitives form a control architecture that is called robotic paradigm.

Three fundamental paradigms have been proposed.

2. Reactive paradigm represents reactive control.

3. Hybrid paradigm combines reactive and deliberative.

1. Hierarchical paradigm is a purely deliberative system.

Examples of Hierarchical Models

It works under the closed world assumption.

 It uses a generalized algorithm for planning. ■ General Problem Solver - STRIPS

It is deliberative architecture.

Stanford Research Institute Problem Solver

### Nested Hierarchical Controller

The world model contains everything the robot needs to know

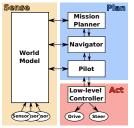

■ The robot senses the environment and creates the "world model"

• The advantage is in ordering the relationship between the primitives. It is a direct "implementation" of the first AI approach to robotics. Introduced in Shakev, the first AI robot (1967-70).

• Then, the robot plans its action and executes it.

- Decomposition of the planner into three different subsystems: Mission Planner, Navigation, Pilot.
- Navigation is planning a path as a sequence of waypoints.
- Pilot generates an action to follow the path. It can response to sudden objects in the navigation

course. The plan exists, and it is not necessary to perform complete planning.

# Disadvantages of the Hierarchical Model

- Disadvantages are related to planning and its computational requirements.
- Planning can be very slow and the "global world" representation has to contain further all information needed for planning. Sensing and acting are always disconnected.
- The "global world" representation has to be up-to-date.
  - The world model used by the planner has to be frequently updated to achieve a sufficient accuracy for the particular task.
- A general problem solver needs many facts about the world to search for a solution.
- Searching for a solution in a huge search space is quickly computationally intractable, and the problem is related to the so-called frame problem.
  - Even simple actions need to reason over all (irrelevant) details.
- Frame problem is a problem of representing real-world situations to be computationally tractable. Decomposition of the world model into parts that best fit the type of actions.

It was used until 1980, when the focus was changed to the reactive paradigm.

Despite drawbacks of the hierarchical paradigm, it has been deployed in various systems,

■ The development of hierarchical models further exhibited additional advancements such as a potential to address the frame problem.

e.g., Nested Hierarchical Controller and NIST Realtime Control System.

- They also provide a way to organize the particular blocks of the control architecture.
- Finally, the hierarchical model represents an architecture that supports evolution and learning systems towards fully autonomous control.

# NIST Real-time Control System (RCS)

- Motivated to create a guide for manufacturers to add intelligence to their robots.
- It is based on the NHC, and the main feature it introduces is a set of models for sensory perception.
- It introduces preprocessing step between the sensory perception and a world model.
- The sensor preprocessing is called feature extraction such as following.
  - An extraction of the relevant information for creating a model of the environment, such as salient objects utilized for localization.
- It also introduced the so-called Value Judgment module.
  - After planning, it simulates the plan to ensure its feasibility.
- Then, the plan is passed to Behavior Generation module to convert the plans into actions that are performed (Act).

The "behavior" is further utilized in reactive and hybrid architectures.

How to implement the computational theory? What is the representation of input and output? What is the algorithm for the transformation of input to output?

Hierarchical Paradigm – Summary Hierarchical paradigm represents deliberative architecture also called sense-plan-act.

The robot control is decomposed into functional modules that are sequentially executed.

Several architectures have been proposed, e.g., using STRIP planner in Shakey, Nested

Despite the drawbacks, hierarchical architectures tend to support the evolution of in-

Agent and Computational-Level Theory

It has centralized representation and reasoning.

May need extensive and computationally demanding reasoning.

Hierarchical Controller (NHC), NIST Real-time Control System (RCS).

telligence from semi-autonomous control to fully autonomous control.

It can interact with the world to make changes and sense the world.

What is the goal of the computation, and why is it relevant?

How to physically realize the representation and algorithm?

The reactive paradigm is influenced by Computational-Level Theories.

Encourage open loop execution of the generated plans.

Agent is a self-contained and independent entity.

■ Computational Level - What? and Why?

Navlah vehicles 1-5

The output of the sense module is the input of the plan module, etc.

■ Algorithmic level – How?

#### **Behaviors**

Behavior is the mapping of sensory inputs to the pattern of motor action.

- Behaviors can be divided into three categories
  - Reflexive behaviors are "hardwired" stimulus-response (S-R).

connotes a reflexive behavior

Stimulus is directly connected to the response - fastest response time.

Reactive behaviors are learned, and they are then executed without conscious thought.

E.g., Behaviors based on "muscle memory" such as biking and skiing are reactive behaviors.

 Conscious behaviors are deliberative as a sequence of previously developed behaviors. Notice, in ethology, the reactive behavior is the learned behavior, while in robotics, it

Reflexive behaviors are fast "hardwired" – if there is a sense, they produce the action.

Reflexive Behaviors

- It can be categorized into three types.
  - 1. Reflexes the response lasts only as long as the stimulus.
    - The response is proportional to the intensity of the stimulus.
  - 2. Taxes the response to stimulus results in a movement towards or away from the stimulus,
    - e.g., moving to light, warm, etc.
  - 3. Fixed-Action Patterns the response continues for a longer duration than the stimulus.
- The categories are not mutually exclusive.
  - An animal may keep its orientation to the last sensed location of the food source (taxis) even when it loses the "sight" of it (fixed-action patterns).

"Tactile-based" (e.g., model-based) triggering of obstacle avoidance or staircaise locomotion.

initialization steps to learn what the hive looks like Notice, S-R (stimulus-response) types of behaviors are simple to pre-program, but it cer-

tainly should not exclude usage of memory.

# Reactive Paradigm

The reactive paradigm is a connection of sensing with acting.

- It is biologically inspired as humans and animals provide evidence of intelligent behavior in an open world, and thus it may be possible to overcome the close world assump-
- Insects, fish, and other "simple" animals exhibit intelligent behavior without virtually no
- There must be the same mechanism that avoids the frame problem.
- For further discussion, we need some terms to discuss the properties of "intelligence" of various entities.

It has self-awareness.

Four Ways to Acquire a Behavior

■ Physical level – How to implement the process?

Ethology provides insights into how animals might acquire and organize behaviors.

Focus on the process rather than the implementation

1. Innate - be born with a behavior, e.g., be pre-programmed. 2. Sequence of innate behaviors - be born with the sequence.

The sequence is logical but important.

Each step is triggered by the combination of the internal state and the environment.

3. Innate with memory - be born with behaviors that need initialization. E.g., a bee does not bear with the known location of the hive. It has to perform some

4. Learn - to learn a set of behaviors

### Releasing Behavior - When to Stop/Suppress the Behavior

- The internal state and/or motivation may release the behavior.
  - Being hungry results in looking for food.
- Behaviors can be sequenced into complex behavior.
- Innate releasing mechanism is a way to specify when behavior gets turned on/off.
- The releaser acts as a control signal to activate behavior.
  - If the behavior is not released, it does not respond to sensory inputs, and it does not produce the motor outputs. Releaser The releaser filters the perception.

■ The releasers can be compound – multiple conditions have to be satisfied to release the behavior.

#### Concurrent Behaviors

- Behaviors can execute concurrently and independently, resulting in different interactions.
  - Equilibrium the behaviors seem to balance each other out.
  - E.g., an undecided behavior of squirrel whether to go for food or rather run avoiding human. Dominance of one - winner takes all as only one behavior can execute and not both simultaneously
  - Cancellation the behaviors cancel each other out.

E.g., one behavior going to light and the second behavior going out of the light.

- It is (might) not (be) known how different mechanisms for conflicting behaviors are employed
- However, it is important to be aware how the behaviors will interact in a robotic system.

Multiple. Concurrent Behaviors

Strictly speaking, one behavior does not know what another behavior is doing or per-

Allows actions without memory, inference, or interpretation

- Direct perception reduces the computational complexity of sense. Behaviors are independent, but the output from one behavior:
  - Can be combined with another to produce the output;

1. Robots are situated agents operating in an ecological niche.

May serve to inhibit another behavior.

tation is avoided - ego-centric representation.

Behaviors can be tested independently.

Behaviors Summary Behavior is a fundamental element in biological intelligence and a fundamental compo-

Complex actions can be decomposed into independent behaviors that couple sensing

and acting.

perception).

Characteristics of Reactive Behaviors

Robot has its intentions and goals; it changes the world by its actions, and what it

2. Behaviors serve as the building blocks for robotic actions, and the overall behavior of

3. Only local, behavior-specific sensing is permitted - usage of explicit abstract represen-

4. Reactive-based systems follow good software design principles – modularity of behaviors

### Reactive Paradigm

 Reactive paradigm originates from dissatisfaction with the hierarchical paradigm (S-P-A), which is influenced by ethology.

- - Behaviors are layered, where lower layers are "survival" behaviors.
  - Upper layers may reuse the lower, inhibit them, or create parallel tracks of more advanced behaviors. If an upper layer fails, the bottom layers would still operate.

 Mechanisms for handling simultaneously active multiple behaviors are needed for complex reactive architectures.

- Two main representative methods have been proposed in the literature.
  - Subsumption architecture proposed by Rodney Brooks.

Behavior

Behavior

Behavior

SENSE

Potential fields methodology studied by Ronald Arkin, David Payton, et al.

supports decomposition of a task into particular behaviors. Behaviors can be created from other (primitive) behaviors.

5. Reactive-based systems or behaviors are often biologically inspired

Under reactive paradigm, it is acceptable to mimic biological intelligence.

E.g., robot-centric coordinates of an obstacle are relative and not in the world coordinates.

# An Overview of Subsumption Architecture

- Subsumption architecture has been deployed in many robots that exhibit walk, collision avoidance, etc. without the "move-think-move-think" pauses of Shakev.
- Behaviors are released in a stimulus-response way.
- Modules are organized into layers of competence.
  - 1. Modules at the higher layer can override (subsume) the output from the behaviors of the lower layer

Winner-take-all - the winner is the higher layer.

2 Internal states are avoided

A good behavioral design minimizes the internal states that can be, e.g., used in releasing behavior.

- 3. A task is accomplished by activating the appropriate layer that activates a lower layer and so on
- In practice, the subsumption-based system is not easily taskable.

It needs to be reprogrammed for a different task; however, it can serve well for the defined task.

# Hybrid Paradigm

- The main drawback of reactive-based architectures is a lack of planning and reasoning about the world.
  - An example is a robot that cannot plan an optimal trajectory.
- Hybrid architecture combines the hierarchical (deliberative) paradigm with the reactive paradigm. Beginning of the 1990's

- Hybrid architecture can be described as Plan, then Sense-Act.
  - Planning covers a relatively long time horizon, and it uses a global world model.
- Sense-Act covers the reactive (real-time) part of the control.

### Characteristics of Reactive Paradigm in Hybrid Paradigm

- Hybrid paradigm is an extension of the Reactive paradigm.
- The term behavior in the hybrid paradigm includes reflexive, innate, and learned behav-

In the reactive paradigm, it connotes purely reflexive behaviors.

- Behaviors are also sequenced over time, and more complex emergent behaviors can
- Behavioural management planning which behavior to use requires information outside the particular model (a global knowledge).

Reactive behavior works without any outside knowledge.

- Performance monitor evaluates if the robot is making progress toward its goal. For example, whether the robot is moving or stuck.
  - In order to monitor the progress, the program has to know the behavior the robot is trying to accomplish

**Obstacle Avoidance** 

(CVM - Curvature Velocity Method)

# Components of Hybrid Deliberative/Reactive Paradigm

- Sequencer generates a set of behaviors to accomplish a subtask.
- Resource Manager allocates resources to behaviors, which can include a selection of suitable sensors. In reactive architectures, resources for behaviors are usually hardcoded.
- Cartographer creates, stores, and maintains a map or spatial information, a global world model, and knowledge representation. It can be a map but not necessarily.
- Mission Planner interacts with the operator and transforms the commands into the
  - Construct a mission plan. For a mobile robot, it can consist of navigation to some place where further action is taken.
- Performance Monitoring and Problem Solving it is a sort of self-awareness allowing the robot to monitor its progress.

# Existing Hybrid Architectures

- Managerial architectures use agents for high-level planning at the top; then there are agents for plan refinement to the reactive behaviors at the lowest level.
  - E.g., Autonomous Robot Architecture, and Sensor Fusion Effects.
- State-Hierarchy architectures organize activity by the scope of the time knowledge
- Model-Oriented architectures concentrate on symbolic manipulation around the global

#### Example of Reactive Collision Avoidance

- Biologically inspired reactive architecture with vision sensor and CPG.
  - CPG-based locomotion control can be parametrized to steer the robot motion to the left or right.
  - oiding collisions with obstacles and intercepting objects is based on the visual perception inspired by the Lobula Giant Movement Detector (LGMD), which is a neural network detecting approaching objects.

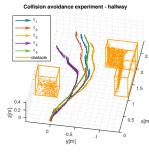

A mapping function:  $\Phi$  from the output of the LGMD vision system to the turn parameter of the CPG

for abs(e) > 0.2 $10000 \cdot \text{sgn}(e)$  for abs(e) < 0.2

# Example of LGMD-based Collision Avoidance

■ LGMD output together with the proposed mapping function provide a smooth motion of the robot.

Čížek, Faigl (Bioinspiration & Biomi

 A general control schema for a mobile robot consists of Perception Module, Localization and Mapping Module, Path Planning Module, and Motion Control Module

A Control Schema for a Mobile Robot

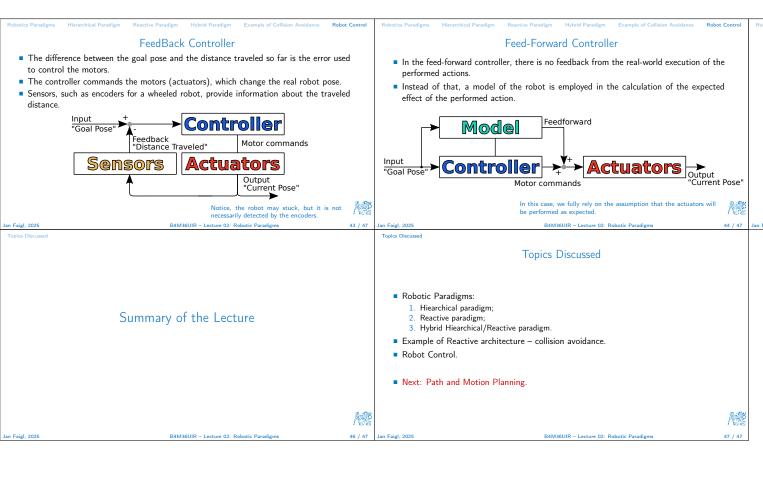

In B4M36UIR, we focus on Path Plann

### Motion Control

- An important part of navigation is the execution of the planned path.
- Motion control module is responsible for the path realization.
  - Position control aims to navigate the robot to the desired location.
  - Path-Following is a controller that aims to navigate the robot along the given path.
  - Trajectory-Tracking differs from the path-following in that the controller forces the robot to reach and follow a time parametrized reference (path).

E.g., a geometric path with an associated timing law.

- The controller can be realized as one of two types:
  - Feedback controller:
  - Feedforward controller

### Temporal Decomposition of Control Layers

- The robot control architecture typically consists of several modules (behaviors) that may run at different frequencies.
- Low-level control is usually the fastest, while path planning is slower as the robot needs some time to reach the desired location.
- An example of possible control frequencies of different control layers.
