Piano Mover's Problem

A classical motion planning problem

Having a CAD model of the piano, model of the environment, the problem is how to move the

We need notion of model representations and formal definition of the problem.

Moreover, we also need a context about the problem and realistic assumptions.

Notation

 $\blacksquare$   $\mathcal{W}$  – World model describes the robot workspace and its boundary determines the

A Robot is defined by its geometry, parameters (kinematics) and it is controllable by

A concept to describe possible configurations of the robot. The robot's configuration

completely specify the robot location in  ${\mathcal W}$  including specification of all degrees of

• Let  $\mathcal{A}$  be a subset of  $\mathcal{W}$  occupied by the robot,  $\mathcal{A} = \mathcal{A}(q)$ .

Overview of the Lecture

Path (Motion) Planning / Trajectory Planning

robot and workspace

Mission Planning

Problem

Robot Control

### Robot Motion Planning – Motivational problem

■ How to transform high-level task specification (provided by humans) into a low-level description suitable for controlling the actuators?

To develop algorithms for such a transformation.

The motion planning algorithms provide transformations how to move a robot (object) considering all operational constraints.

obstacles  $O_i$ .

the motion plan.

■ C – Configuration space (C-space)

A subset of C occupied by obstacles is

■ Collision-free configurations are

The plans have to be admissible and feasible

Basic motion planning algorithms are focused primarily on rotations and translations

Trajectory Generation

## Path / Motion Planning Problem

Sensing and Acting

■ Path is a continuous mapping in C-space such that

$$\pi: [0,1] \to \mathcal{C}_{free}, \text{ with } \pi(0) = q_0, \text{ and } \pi(1) = q_f.$$

• Trajectory is a path with explicit parametrization of time, e.g., accompanied by a description of the motion laws  $(\gamma:[0,1]\to\mathcal{U}$ , where  $\mathcal{U}$  is robot's action space).

 $[T_0, T_f] \ni t \rightsquigarrow \tau \in [0, 1] : q(t) = \pi(\tau) \in \mathcal{C}_{free}$ 

The path planning is the determination of the function  $\pi(\cdot)$ .

Additional requirements can be given:

- Smoothness of the path;
- Kinodynamic constraints, e.g., considering friction forces;
- Optimality criterion shortest vs fastest (length vs curvature).
- Path planning planning a collision-free path in C-space.
- Motion planning planning collision-free motion in the state space.

Real Mobile Robots

In a real deployment, the problem is more complex.

- The world is changing.
- Robots update the knowledge about the environment.

localization, mapping and navigation

• New decisions have to be made based on the feedback from the environment Motion planning is a part of the mission replanning loop.

Multi-robot exploration of unknown environment.

An example of robotic mission:

Josef Štrunc, Bachelor thesis, CTU, 2009.

How to deal with real-world complexity?

Relaxing constraints and considering realistic assumptions.

 $C_{obs} = \{q \in C : A(q) \cap O_i, \forall i\}.$ 

 $C_{free} = C \setminus C_{obs}$ .

E.g., a robot with rigid body in a plane  $C = \{x, y, \varphi\} = \mathbb{R}^2 \times S^1$ .

Example of  $\mathcal{C}_{obs}$  for a Robot with Rotation Representation of C-space Planning in C-space Robot path planning for a disk-shaped robot with a radius  $\rho$ . How to deal with continuous representation of C-space? Continuous Representation of C-space Discretization processing critical geometric events, (random) sampling roadmaps, cell decomposition, potential field Point robot Graph Search Techniques BFS, Gradient Search, A\* Motion planning problem in Motion planning problem in A simple 2D obstacle → has a complicated Cobs geometrical representation of W. Deterministic algorithms exist. C-space has been obtained by enlarging obstacles by the disk A with the radius  $\rho$ . Requires exponential time in C dimension, J. Canny, PAMI, 8(2):200-209, 1986. By applying Minkowski sum:  $\mathcal{O} \oplus \mathcal{A} = \{x + y \mid x \in \mathcal{O}, y \in \mathcal{A}\}$  Explicit representation of C<sub>free</sub> is impractical to compute. Path Planning Methods Path Planning Methods Planning Methods - Overview Visibility Graph Minimal Construct: Efficent Shortest Path in Polygonal Maps 1. Compute visibility graph. (selected approaches) ■ Minimal Construct algorithm computes visibility graph during the A\* search instead of first computation of the 2. Find the shortest path. E.g., by Dijkstra's algorithm. complete visibility graph and then finding the shortest path using A\* or Dijkstra algorithm. ■ Point-to-point path/motion planning. Multi-goal path/motion/trajectory planning later Based on A\* search with line intersection tests are delayed until they become necessary ■ Roadmap based methods - Create a connectivity graph of the free space. The intersection tests are further accelerated using bounding Visibility graph; (Complete but impractical) Cell decomposition; Voronoi graph. Discretization into a grid-based (or lattice-based) representation (Resolution complete) ■ Potential field methods (Complete only for a "navigation function", which is hard to compute Classic path planning algorithms ■ Randomized sampling-based methods Problem Visibility graph Found shortest path Creates a roadmap from connected random samples in Cfree. Constructions of the visibility graph: Probabilistic roadmaps. Samples are drawn from some distribution. Naïve – all segments between n vertices of the map O(n³); Very successful in practice. Minimal Construct: Efficient Shortest Path Finding for Mobile Robots in Using rotation trees for a set of segments – O(n²). M. H. Overmars and E. Welzl, 1988 Path Planning Methods Voronoi Graph Visibility Graph vs Voronoi Graph Cell Decomposition Visibility graph 1. Decompose free space into parts. 1. Roadmap is Voronoi graph that maximizes clearance from the obstacles. Any two points in a convex region can be directly connected by a 2. Start and goal positions are connected to the graph. Shortest path, but it is close to obstacles. We have to consider safety 2. Create an adjacency graph representing the connectivity of the free space. of the path. 3. Path is found using a graph search algorithm 3. Find a path in the graph. An error in plan execution can lead to a Trapezoidal decomposition Complicated in higher dimensions Voronoi graph It maximize clearance, which can provide conservative paths. Small changes in obstacles can lead to large changes in the graph. Complicated in higher dimensions.

A combination is called Visibility-Voronoi - R. Wein, J. P. van den Berg,

For higher dimensions we need other types of roadmaps.

D. Halperin, 2004.

Voronoi graph

Path in graph

B4M36UIR - Lecture 03: Path Planning

Found path

Centroids represent cells

Other decomposition (e.g., triangulation) are possible.

Connect adjacency cells

Find path in the adjacency graph

Path Planning Methods Path Planning Methods Shortest Path Map (SPM) Approximate Shortest Path and Navigation Mesh Point Location Problem • For a given partitioning of the polygonal domain into a discrete set of cells, determine the cell

> Navigation Mesh In addition to robotic approaches, fast shortest path queries are studied in computer games.

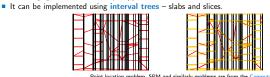

- Speedup computation of the shortest path towards a particular goal location  $p_{\sigma}$  for a polygonal domain  $\mathcal{P}$  with n vertices.
- A partitioning of the free space into cells with respect to the particular location  $p_{\sigma}$ .
- Each cell has a vertex on the shortest path to  $p_{\varepsilon}$ .
- Shortest path from any point p is found by determining the cell (in  $O(\log n)$  using point location alg.) and then travesing the shortest path with up to k bends, i.e., it is found in  $O(\log n + k)$ .
- Determining the SPM using "wavefront" propagation based on continuous Dijkstra paradigm.
- Joseph S. B. Mitchell: A new algorithm for shortest paths among obstacles in the plane, Annals of Mathematics and Artificial Intelligence, 3(1):83–105, 1991. ■ SPM is a precompute structure for the given  $\mathcal{P}$  and  $p_g$ ;
  - single-point query.

There is a class of algorithms based on navigation mesh.

A supporting structure representing the free space.

Masato Edahiro, Iwao Kokubo and Takao Asano: A new point-location

for a given point p.

Path Planning Methods

of the cell vertex

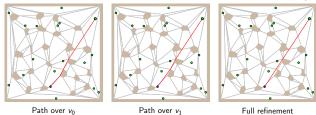

triangulation (convex partitioning).

configuration of the robot.

(Faigl, 2010)

### Path Refinement

- Testing collision of the point p with particular vertices of the estimation of the shortest path.
  - Let the initial path estimation from p to  $p_{\sigma}$  be a sequence of k vertices  $(p, v_1, \dots, v_k, p_{\sigma})$ .
  - We can iteratively test if the segment  $(p, v_i)$ ,  $1 < i \le k$  is collision free up to  $(p, p_g)$ .

Path Planning Methods

It usually originated from the grid based maps, but it is represented as CDT - Constrained

E.g., Polyanya algorithm based on navigation mesh and best-first search.

• Such a function is called navigation function and  $-\nabla f(q)$  points to the goal. • Create a potential field that will attract robot towards the goal  $q_f$  while obstacles will generate repulsive potential repelling the robot away from the obstacles.

• We can use any convex partitioning of the polygonal map to speed up shortest path queries.

2. Then, an estimation of the shortest path from p to  $p_g$  is the shortest path among the one

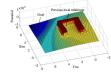

• The estimation can be further improved by "ray-shooting" technique combined with walking in

Artificial Potential Field Method

• The idea is to create a function f that will provide a direction towards the goal for any

Grid-based Planning

1. Precompute all shortest paths from map vertices to  $p_{\sigma}$  using visibility graph.

The navigation function is a sum of potentials.

Such a potential function can have several local minima

# Avoiding Local Minima in Artificial Potential Field

Consider harmonic functions that have only one extremum

$$\nabla^2 f(q) = 0.$$

• Finite element method with defined Dirichlet and Neumann boundary conditions.

J. Mačák, Master thesis, CTU, 2009

# Part II

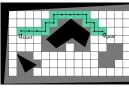

Part 2 - Grid and Graph based Path Planning Methods

## A subdivision of C<sub>free</sub> into smaller cells.

- Grow obstacles can be simplified by growing borders by a diameter of the robot.
- Construction of the planning graph G = (V, E) for V as a set of cells and E as the neighbor-relations.

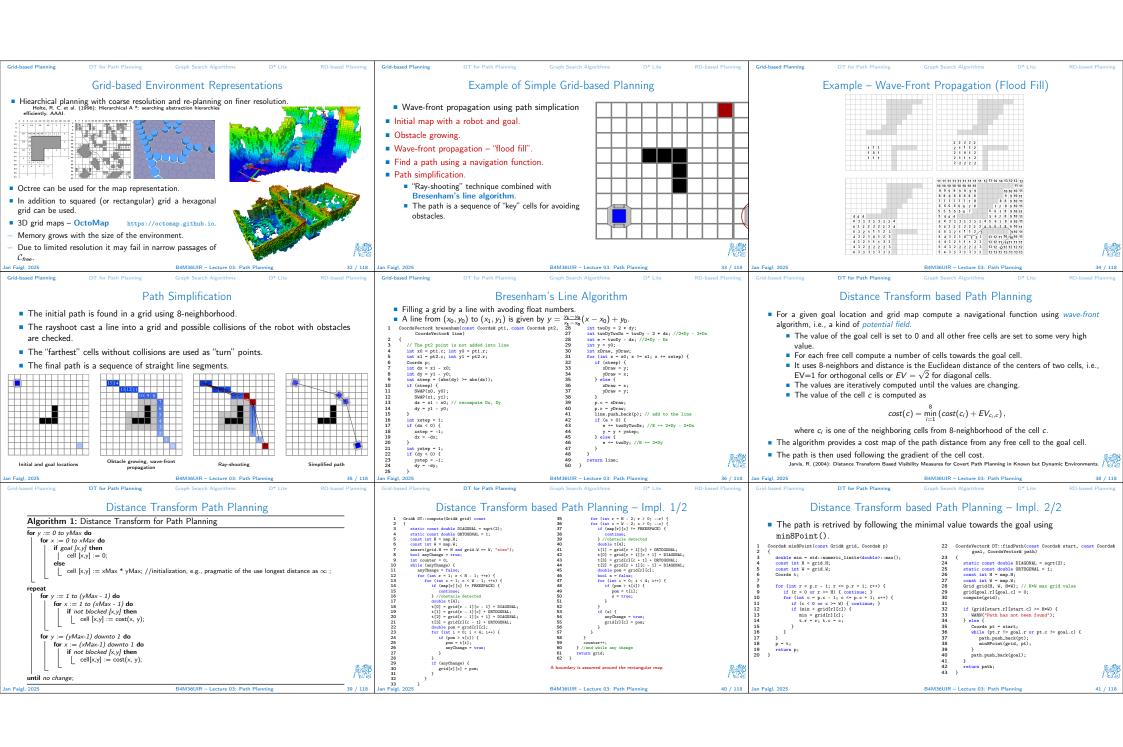

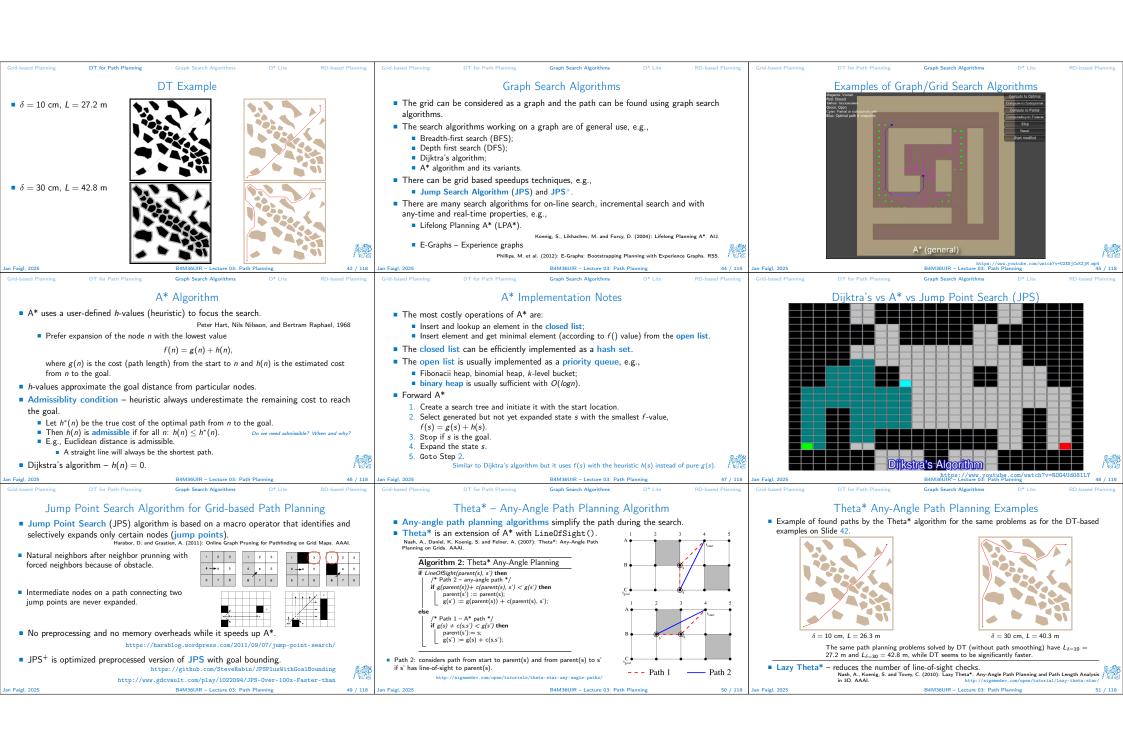

A grid map can be constructed from the so-called occupancy grid maps.

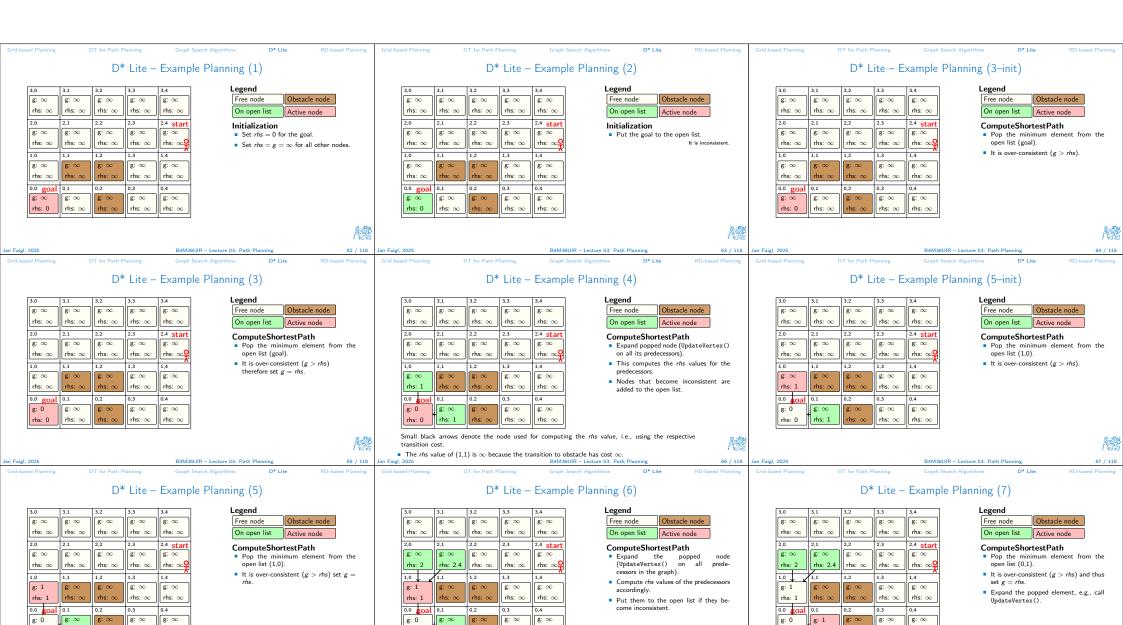

Graph Search Algorithms Real-Time Adaptive A\* (RTAA\*) D\* Lite - Demo A\* Variants – Online Search • The state space (map) may not be known exactly in advance. Environment can dynamically change. True travel costs are experienced during the path execution. Execute A\* with limited look-ahead. while  $(s_{curr} \notin GOAL)$  do Repeated A\* searches can be computationally demanding. Learns better informed heuristic from astar(lookahead); Incremental heuristic search the experience, initially h(s), e.g., Euif s' = FAILURE then Repeated planning of the path from the current state to the goal. | return FAILURE: clidean distance. Planning under the free-space assumption. Reuse information from the previous searches (closed list entries). Look-ahead defines trade-off between for all  $s \in CLOSED$  do ■ Focused Dynamic A\* (D\*) - h\* is based on traversability, it has been used, e.g., for the optimality and computational cost. H(s) := g(s') + h(s') - g(s);Mars rover "Opportunity" execute(plan); // perform one step astar(lookahead) Stentz, A. (1995): The Focussed D\* Algorithm for Real-Time Replanning. IJCAI. A\* expansion as far as "lookahead" nodes return SUCCESS: ■ D\* Lite - similar to D\* and it terminates with the state s'. Koenig, S. and Likhachev, M. (2005): Fast Replanning for Navigation in Unknown Terrain. T-RO s' is the last state expanded during the previous A\* ■ Real-Time Heuristic Search Repeated planning with limited look-ahead - suboptimal but fast ■ Learning Real-Time A\* (LRTA\*) Korf, E. (1990): Real-time heuristic search. JAI. Real-Time Adaptive A\* (RTAA\*) Koenig, S. and Likhachev, M. (2006): Real-time adaptive A\*. AAMAS. D\* Lite Algorithm D\* Lite Overview D\* Lite: Cost Estimates ■ It is similar to D\*, but it is based on Lifelong Planning A\*. ■ Main - repeat until the robot reaches the goal (or  $g(s_{start}) = \infty$  there is no path). • rhs of the node u is computed based on g of its successors in the graph and the Koenig, S. and Likhachev, M. (2002): D\* Lite. AAAI. Initialize(); transition costs of the edge to those successors It searches from the goal node to the start node, i.e., g-values estimate the goal distance. ComputeShortestPath(); foreach  $s \in S$  do  $\mathit{rhs}(u) = \left\{ \begin{array}{ll} 0 & \text{if } u = s_{\mathit{start}} \\ \min_{s' \in \mathit{Succ}(u)}(g(s') + c(s', u)) & \text{otherwise} \end{array} \right.$ while  $(s_{start} \neq s_{goal})$  do Store pending nodes in a priority queue.  $rhs(s) := g(s) := \infty;$  $s_{start} = \operatorname{argmin}_{s' \in Succ(s_{start})} (c(s_{start}, s') + g(s'));$  $rhs(s_{goal}) := 0;$ U.Insert( $s_{goal}$ , CalculateKey( $s_{goal}$ )) Process nodes in order of increasing objective function value. Move to sstart; Scan the graph for changed edge costs; Incrementally repair solution paths when changes occur. • The key/priority of a node s on the open list is the minimum of g(s) and rhs(s) plus a if any edge cost changed perform then foreach directed edges (u, v) with changed edge Maintains two estimates of costs per node: focusing heuristic h costs do g – the objective function value – based on what we know: Update the edge cost c(u, v);  $[\min(g(s), rhs(s)) + h(s_{start}, s); \min(g(s), rhs(s))].$  rhs - one-step lookahead of the objective function value - based on what we know. UpdateVertex(u); Consistency: foreach  $s \in U$  do ■ Consistent – g = rhs; U.Update(s, CalculateKey(s)); The first term is used as the primary key. Inconsistent − g ≠ rhs. ComputeShortestPath(); ■ The second term is used as the secondary key for tie-breaking. U is priority queue with the vertices. • Inconsistent nodes are stored in the priority queue (open list) for processing. D\* Lite - Demo D\* Lite - Example D\* Lite Algorithm - ComputeShortestPath() Procedure ComputeShortestPath Legend while  $U.TopKey() < CalculateKey(s_{start}) OR rhs(s_{start}) \neq g(s_{start}) do$ Free node Obstacle node u := U.Pop();if g(u) > rhs(u) then On open list Active node g(u) := rhs(u);foreach  $s \in Pred(u)$  do UpdateVertex(s); A grid map of the environment (what is actually known). 8-connected graph superimposed on the grid (bidirectional). foreach  $s \in Pred(u) \bigcup \{u\}$  do UpdateVertex(s); · Focusing heuristic is not used (h = 0)Procedure UpdateVertex  $\text{if } u \neq s_{goal} \text{ then } rhs(u) := \min_{s' \in Succ(u)} (c(u,s') + g(s')); \\$ if  $u \in U$  then U.Remove(u); if  $g(u) \neq rhs(u)$  then U.Insert(u, CalculateKey(u)); Transition costs Procedure CalculateKev return  $[\min(g(s), rhs(s)) + h(s_{start}, s); \min(g(s), rhs(s))]$ Free space - Free space: 1.0 and 1.4 (for diagonal edge). ### D\* Lite - Example Planning (39)

Legend Free node Obstacle node On open list Active node

 Follow the gradient of g values from the robot's current position (node)

## D\* Lite - Comments

- D\* Lite works with real valued costs, not only with binary costs (free/obstacle).
- The search can be focused with an admissible heuristic that would be added to g and
- The final version of D\* Lite includes further optimization (not shown in the example).
  - Updating the rhs value without considering all successors every time.
  - Re-focusing the search as the robot moves without reordering the entire open list.

## Reaction-Diffusion Processes Background

- Reaction-Diffusion (RD) models dynamical systems capable to reproduce the au-
- Autowaves a class of nonlinear waves that propagate through an active media. At the expense of the energy stored in the medium, e.g., grass combustion.
- RD model describes spatio-temporal evolution of two state variables  $u = u(\vec{x}, t)$  and  $v = v(\vec{x}, t)$  in space  $\vec{x}$  and time t

$$\dot{u} = f(u, v) + D_u \triangle u$$

$$\dot{v} = g(u, v) + D_v \triangle v$$

where  $\triangle$  is the Laplacian.

This RD-based path planning is informative, just for curiosity.

RD-based Path Planning - Computational Model

conditions (FTCS).

1. Propagation phase

i.e., constraining concentration levels to some specific values.

## Reaction-Diffusion Background

FitzHugh-Nagumo (FHN) model

FitzHugh R, Biophysical Journal (1961)

$$\dot{u} = \varepsilon \left( u - u^3 - v + \phi \right) + D_u \triangle u$$

$$\dot{v} = \left( u - \alpha v + \beta \right) + D_v \triangle u$$

where  $\alpha, \beta, \epsilon$ , and  $\phi$  are parameters of the model.

• Dynamics of RD system is determined by the associated nullcline configurations for  $\dot{u}=0$ and  $\dot{v}=0$  in the absence of diffusion, i.e.,

$$\varepsilon (u - u^3 - v + \phi) = 0,$$
  

$$(u - \alpha v + \beta) = 0,$$

which have associated geometrical shapes.

Nullcline Configurations and Steady States

- Nullclines intersections represent:
  - Stable States (SSs);
  - Unstable States.
- Bistable regime

The system (concentration levels of (u, v) for each grid cell) tends to be in SSs.

"preference" of SS+ over SS-

- System moves from  $SS^-$  to  $SS^+$ , if a small perturbation is intro-
- The SSs are separated by a mobile frontier a kind of traveling frontwave (autowaves).

2. Contraction phase Different nullclines configuration.

Start and goal positions are forced towards SS+.

■ Terminate when the frontwave reaches the goal.

Freespace is set to SS<sup>-</sup> and the start location SS<sup>+</sup>

Finite difference method on a Cartesian grid with Dirichlet boundary

■ External forcing — introducing additional information

Two-phase evolution of the underlying RD model.

 $discretization 
ightarrow grid \ based \ computation 
ightarrow grid \ map$ Vázquez-Otero and Muñuzuri, CNNA (2010)

SS<sup>-</sup> shrinks until only the path linking the forced points remains.

Parallel propagation of the frontwave with non-annihilation property

## Example of Found Paths

• The path clearance maybe adjusted by the wavelength and size of the computational grid. Control of the path distance from the obstacles (path safety).

Voronoi Diagram Reaction-Diffusion Distance Transform Otero A, Faigl J, Muñuzuri A Beeson P, Jong N, Kuipers B

Comparison with Standard Approaches

RD-based approach provides competitive paths regarding path length and clearance, while they seem to be smooth.

Vázquez-Otero, A., Faigl, J., Duro, N. and Dormido, R. (2014): Reaction-Diffusion based Computational Model for Autonomous Mobile
