B4M36UIR - Artificial Intelligence in Robotics

Probabilistic Roadmaps

A discrete representation of the continuous \mathcal{C} -space generated by randomly sampled

• Edges represent a feasible path (trajectory) between the particular configurations.

• Nodes of the graph represent admissible configurations of the robot.

Overview of the Lecture

■ Part 1 - Randomized Sampling-based Motion Planning Methods

Sampling-Based Methods

other points in C_{free} .

 q_{new} to V if $q_{new} \notin V$.

satisfied.

#1 Given problem domain

or graph search technique.

• If τ is not a collision-free, go to Step 2.

Incremental Sampling and Searching

Single query sampling-based algorithms incrementally create a search graph (roadmap).

2. Vertex selection method – choose a vertex $q_{cur} \in V$ for the expansion.

1. Initialization – G(V, E) an undirected search graph, V may contain q_{start} , q_{goal} and/or

3. Local planning method – for some $q_{new} \in \mathcal{C}_{free}$, attempt to construct a path $\tau: [0,1] \to$

4. Insert an edge in the graph – Insert τ into E as an edge from q_{cur} to q_{new} and insert

5. Check for a solution – Determine if G encodes a solution by using a single search tree

6. Repeat Step 2 - iterate unless a solution has been found or a termination condition is

PRM Construction

 C_{free} such that $\tau(0)=q_{cur}$ and $\tau(1)=q_{new}$, τ must be checked to ensure it is collision

(Randomized) Sampling-based Motion Planning

- It uses an explicit representation of the obstacles in C-space.
- A "black-box" function is used to evaluate if a configuration q is a collision-free using geometrical models of the objects (robot and environment).
- 2D or 3D shapes of the robot and environment can be represented as sets of triangles - tesselated models
- Collision test is then a test of for the intersection of the triangles.
- Collision free configurations form a discrete representation of C_{free} .
- A collision test library RAPID http://gamma.cs.unc.edu/OBB/ Configurations in C_{free} can be sampled randomly and connected to a (probabilistic) roadmap.
- Rather than the full completeness they provide probabilistic completeness or resolution comneteness It is probabilistically complete if for increasing number of samples, an admissible solution would be found (if exists)

Probabilistic Roadmap Strategies

Kavraki, L., Svestka, P., Latombe, J.-C., Overmars, M. H.B: Probabilistic Roadmaps for Pa High Dimensional Configuration Spaces, IEEE Transactions on Robotics, 12(4):566–580, 1996.

Multi-Query strategy is to create a roadmap that can be used for several queries.

Hsu, D., Latombe, J.-C., Kurniawati, H.: On the Probabilistic Founda The International Journal of Robotics Research, 25(7):627–643, 2006.

• For each planning problem, it constructs a new roadmap to characterize the subspace

Generate a single roadmap that is then used for repeated planning queries.

LaValle, S. M.: Planning Algorithms (2006), Chapter 5.4.

An representative technique is Probabilistic RoadMap (PRM).

Single-Query strategy is an incremental approach.

of C-space that is relevant to the problem. Rapidly-exploring Random Tree – RRT;

Multi-Query Strategy

Having the graph, the final path (trajectory) can be found by a graph search technique

Build a roadmap (graph) representing the environment.

- 1. Learning phase
 - 1.1 Sample n points in C_{free} .
- 1.2 Connect the random configurations using a local planner
- - 2.1 Connect start and goal configurations with the PRM.

2.2 Use the graph search to find the path.

Using a local planner.

First planner that demonstrates ability to solve general planning problems in more than 4-5 dimensions.

#3 Connecting sample

Expansive-Space Tree – EST; Sampling-based Roadmap of Trees – SRT.

A combination of multiple-query and single-query approaches. Plaku et al., 2005

LaValle, 1998

Hsu et al., 1997

Path planning problem can be defined by a triplet

• $C_{free} = cl(C \setminus C_{obs}), C = (0, 1)^d, \text{ for } d \in \mathbb{N}, d \geq 2;$

 $q_{init} \in C_{free}$ is the initial configuration (condition);

path – if it is continuous:

Total variation TV(π) is de facto a path length.

planning problem $\mathcal{P} = (\mathcal{C}_{free}, q_{init}, \mathcal{Q}_{goal}),$

It is a "relaxed" notion of the completeness.

Applicable only to problems with a robust solution.

■ Function $\pi: [0,1] \to \mathbb{R}^d$ of bounded variation is called:

Q_{goal} is the goal region defined as an open subspace of C_{free}.

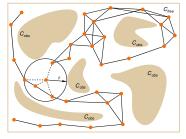

collision-free path – if it is a path and $\pi(\tau) \in \mathcal{C}_{free}$ for $\tau \in [0,1]$;

Path Planning Problem Formulation

 $\mathcal{P} = (\mathcal{C}_{free}, q_{init}, \mathcal{Q}_{goal}), \text{ where }$

Practical PRM

- Incremental construction.
- Connect nodes in a radius r.
- Local planner tests collisions up to selected resolution δ .
- Path can be found by Dijkstra's algo-

What are the properties of the PRM algorithm?

We need a couple of more formalisms.

• feasible – if it is a collision-free path, and $\pi(0) = q_{init}$ and $\pi(1) \in cl(\mathcal{Q}_{goal})$

• A function π with total variation $\mathsf{TV}(\pi) < \infty$ is said to have bounded variation, where $\mathsf{TV}(\pi)$ is the

 $TV(\pi) = \sup_{n \in \mathbb{N}, 0 = \tau_0 < \tau_1 < ... < \tau_n = s} \sum_{i=1}^{n} |\pi(\tau_i) - \pi(\tau_{i-1})|.$

Probabilistic Completeness 2/2 An algorithm \mathcal{ALG} is probabilistically complete if, for any robustly feasible path

 $\lim_{n\to\infty} \Pr(\mathcal{ALG} \text{ returns a solution to } \mathcal{P}) = 1.$

Probabilistic Completeness 1/2

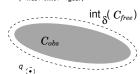

First, we need robustly feasible path planning problem (C_{free} , q_{init} , Q_{goal})

- $q \in \mathcal{C}_{free}$ is δ -interior state of \mathcal{C}_{free} if the closed ball of radius δ centered at q lies entirely inside \mathcal{C}_{free} .
- δ -interior of \mathcal{C}_{free} is $\operatorname{int}_{\delta}(\mathcal{C}_{free}) = \{q \in \mathcal{C}_{free} | \mathcal{B}_{f,\delta} \subseteq \mathcal{C}_{free} \}$ A collection of all δ -interior states.
- A collision free path π has strong δ -clearance, if π lies entirely inside $int_{\delta}(C_{free})$.

int (C_{free})

Asymptotic Optimality 2/4 – Weak δ -clearance

• A collision-free path $\pi:[0,s]\to\mathcal{C}_{free}$ has weak δ -clearance if there exists a path π' that has strong δ -clearance and homotopy ψ with $\psi(0) = \pi$, $\psi(1) = \pi'$, and for all

a distance & away from obstacles

class as π .

 $\alpha \in (0,1]$ there exists $\delta_{\alpha} > 0$ such that $\psi(\alpha)$ has strong δ -clearance.

int $_{\delta}$ (C_{free})

int $_{S}(C_{free})$

Asymptotic Optimality 3/4 - Robust Optimal Solution

- Asymptotic optimality is applicable with a robust optimal solution that can be obtained as a limit of robust (non-optimal) solutions.
- A collision-free path π^* is robust optimal solution if it has weak δ -clearance and for any sequence of collision free paths $\{\pi_n\}_{n\in\mathbb{N}}, \pi_n\in\mathcal{C}_{free}$ such that $\lim_{n\to\infty}\pi_n=\pi^*$,

$$\lim_{n\to\infty}c(\pi_n)=c(\pi^*)$$

There exists a path with strong δ -clearance, and π^* is homotopic to such

• Weak δ -clearance implies an existence of the strong δ -clearance path within the some homotopy, and thus robustly feasible solution problem.

Thus, it implies the probabilistic completeness

■ Feasible path planning

For a path planning problem (C_{free} , q_{init} , Q_{goal}):

■ Find a feasible path $\pi:[0,1]\to \mathcal{C}_{free}$ such that $\pi(0)=q_{init}$ and $\pi(1)\in \operatorname{cl}(\mathcal{Q}_{goal})$, if such

Path Planning Problem

Report failure if no such path exists.

Optimal path planning

The optimality problem asks for a feasible path with the minimum cost.

For $(C_{free}, q_{init}, \mathcal{Q}_{goal})$ and a cost function $c : \Sigma \to \mathbb{R}_{\geq 0}$:

- Find a feasible path π^* such that $c(\pi^*) = \min\{c(\pi) : \pi \text{ is feasible}\};$
- Report failure if no such path exists.

The cost function is assumed to be monotonic and bounded There exists k_c such that $c(\pi) \le k_c \, TV(\pi)$.

Asymptotic Optimality 1/4 - Homotopy

Asymptotic optimality relies on a notion of weak δ -clearance.

Notice, we use strong δ -clearance for probabilistic completeness

- We need to describe possibly improving paths (during the planning).
- Function $\psi: [0,1] \to \mathcal{C}_{free}$ is called homotopy, if $\psi(0) = \pi_1$ and $\psi(1) = \pi_2$ and $\psi(\tau)$ is collision-free path for all $\tau \in [0, 1]$.
- A collision-free path π_1 is homotopic to π_2 if there exists homotopy function ψ . A path homotopic to π can be continuously transformed to π through C_{free}

Asymptotic Optimality 4/4 – Asymptotically Optimal Algorithm

An algorithm \mathcal{ALG} is asymptotically optimal if, for any path planning problem $\mathcal{P} =$ $(C_{free}, q_{init}, Q_{goal})$ and cost function c that admits a robust optimal solution with the finite cost c^* such that

$$Pr\left(\left\{\lim_{i o\infty}Y_i^{\mathcal{ALG}}=c^*
ight\}
ight)=1.$$

 $Y_i^{\mathcal{ALG}}$ is the extended random variable corresponding to the minimum-cost solution included in the graph returned by \mathcal{ALG} at the end of the iteration i.

We need the strong δ -clearance to find π' (by randomized sampling). Then, such a path can be (localy) improved (shorten) towards the shortest π . π' must be within the same homotopy class (passing obstacles at the same way as the optimal path π) to guarantee such a path π can be the optimal path.

Weak δ -clearance does not require points along a path to be at least

 A path π with a weak δ-clearance. π' lies in int_δ(C_{free}) and it is the same homotopy

Properties of the PRM Algorithm

Completeness for the standard PRM has not been provided when it was introduced.

What are the differences between PRM and sPRM?

A simplified version of the PRM (called sPRM) has been most studied.

Algorithm 1: PRM

 $V \leftarrow \emptyset; E \leftarrow \emptyset;$

Input: q_{init} , the number of samples n, and radius nOutput: PRM – G = (V, E)

 $V \leftarrow V \cup \{q_{rand}\};$ foreach $u \in U$ with increasing $||u - q_r||$ do if q_{rand} and u are not in the same

connected component of G = (V, E)

if CollisionFree(q_{rand}, u) then $E \leftarrow E \cup \{(q_{rand}, u), (u, q_{rand})\}$

 $q_{rand} \leftarrow SampleFree;$ $U \leftarrow Near(G = (V, E), q_{rand}, r);$

Algorithm 2: sPRM

radius rOutput: PRM – G = (V, E)

foreach $u \in U$ do if CollisionFree(v, u) then

return G = (V, E);

Input: q_{init}, the number of samples n, and

 $V \leftarrow \{q_{init}\} \cup \{SampleFree_i\}_{i=1,...,n-1}; E \leftarrow \emptyset;$ foreach $v \in V$ do

 $E \leftarrow E \cup \{(v, u), (u, v)\};$

 Connections between vertices in the same con nected component are allowed

The radius r is fixed and can be relatively long;

 $U \leftarrow \text{Near}(G = (V, E), v, r) \setminus \{v\};$

thus sPRM can be very demanding.

PRM vs. simplified PRM (sPRM)

- sPRM (simplified PRM):
 - Probabilistically complete and asymptotically optimal.
 - Processing complexity can be bounded by O(n²)
 - Query complexity can be bounded by O(n²).
 - Space complexity can be bounded by O(n²).
- Heuristics practically used are not necessarily probabilistic complete and asymptotically optimal.

PRM – Properties

- k-nearest sPRM is not probabilistically complete for k = 1.
- Variable radius sPRM is not probabilistically complete; with the radius $r(n) = \gamma n^{-\frac{1}{d}}$.

Rapidly Exploring Random Tree (RRT)

1. Start with the initial configuration q_0 , which is a root of the constructed graph (tree).

5. Go to Step 2 until the tree is within a sufficient distance from the goal configuration.

See Karaman and Frazzoli: Sampling-based Algorithms for Optimal Motion Planning, IJRR 2011.

PRM algorithm

- + It has very simple implementation.
- + It provides completeness (for sPRM)
- Differential constraints (car-like vehicles) are not straightforward (but possible).

2. Generate a new random configuration q_{new} in C_{free} . 3. Find the closest node q_{near} to q_{new} in the tree.

It incrementally builds a graph (tree) towards the goal area.

It does not guarantee precise path to the goal configuration

KD-tree implementation like ANN or FLANN libraries can be utilized.

Extend the tree by a small step or using a direct control $u \in U$ that will move

Rapidly Exploring Random Tree (RR)

Using the Oraculum

Single-Query algorithm.

Extend q_{near} towards q_{new}.

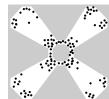

sPRM is probabilistically complete.

Comments about Random Sampling 1/2

Different sampling strategies (distributions) may be applied

- Notice, one of the main issues of the randomized sampling-based approaches is the narrow passage.
- Several modifications of sampling-based strategies have been proposed in the last decades.

return G = (V, E);

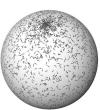

Several ways for the set U of vertices to connect them can improved the performance, such as k-nearest

neighbors to v; or variable connection radius r as a function of n at the cost of lost of asymptotical optimality

Comments about Random Sampling 2/2

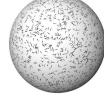

- A solution can be found using only a few samples.
- Sampling strategies are important: Near obstacles; Narrow passages; Grid-based; Uniform sampling must be carefully considered.

James J. Kuffner (2004): Effective Sampling and Distance Metrics for 3D Rigid Body Path Planning, ICRA, 2004.

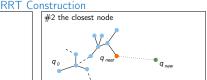

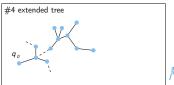

Uniform sampling of SO(3) using Euler angles

Or terminates after dedicated running time

#1 new random configuration

RRT Algorithm

- Motivation is a single query and control-based path finding.
- It incrementally builds a graph (tree) towards the goal area.

Algorithm 3: Rapidly Exploring Random Tree (RRT)

Input: q_{init}, number of samples n Output: Roadmap G = (V, E) $V \leftarrow \{q_{init}\}; E \leftarrow \emptyset;$ $q_{rand} \leftarrow \mathsf{SampleFree}$ $q_{nearest} \leftarrow Nearest(G = (V, E), q_{rand});$ $q_{new} \leftarrow Steer(q_{nearest}, q_{rand});$ if CollisionFree(qnearest, qnew) then $V \leftarrow V \cup \{x_{new}\}; E \leftarrow E \cup \{(x_{nearest}, x_{new})\};$ return G = (V, E);

nical Report 98-11, Computer Science Dept., Iowa State University, 1998.

Properties of RRT Algorithms

■ The RRT algorithm rapidly explores the space.

the robot to the position closest to q_{new} applied for δt .

q_{new} will more likely be generated in large, not yet covered parts (voroni bias).

- Allows considering kinodynamic/dynamic constraints (during the expansion).
- Can provide trajectory or a sequence of direct control commands for robot controllers.
- A collision detection test is usually used as a "black-box."

RAPID. Bullet libraries.

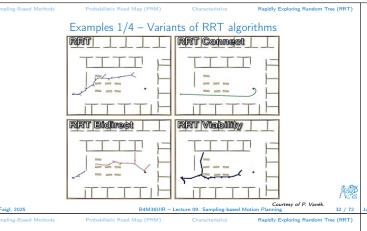

- Similarly to PRM, RRT algorithms have poor performance in narrow passage problems.
- RRT algorithms provide feasible paths.

It can be relatively far from an optimal solution; according to the length of the path.

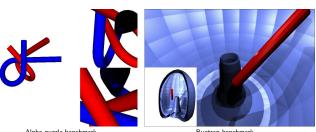

Many variants of the RRT have been proposed in the literature.

Planning on a 3D surface

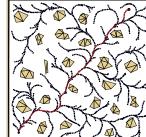

Control-Based Sampling

- Select a configuration q from the tree T of the current configurations.
- Pick a control input $\overrightarrow{u} = (v, \varphi)$ and the integrate system (motion) equation over a short period Δt :

$$\begin{pmatrix} \Delta x \\ \Delta y \\ \Delta \phi \end{pmatrix} = \int_t^{t+\Delta t} \begin{pmatrix} v\cos\phi \\ v\sin\phi \\ \frac{v}{t}\tan\varphi \end{pmatrix} dt.$$

If the motion is collision-free, add the endpoint to the tree.

Considering k configurations for $k\delta t = dt$.

- PRM and RRT are theoretically probabilistic complete.
- They provide a feasible solution without quality guarantee.
- In 2011, a systematical study of the asymptotic behavior of randomized sampling-based It builds on properties of Random Geometric Graphs (RGG) introduced by Gilbert (1961) and further studied by Penrose (1999).

Optimal Motion Planners

RRT and Quality of Solution 2/2

- RRT does not satisfy a necessary condition for the asymptotic optimality.
 - For $0 < R < \inf_{q \in Q_{soal}} ||q q_{init}||$, the event $\{\lim_{n \to \infty} Y_n^{RTT} = c^*\}$ occurs only if the k-th branch of the RRT contains vertices outside the R-ball centered at qinit for infinitely

See Appendix B in Karaman and Frazzoli, 2011.

• It is required the root node will have infinitely many subtrees that extend at least a distance ϵ away from q_{init}

The sub-optimality is caused by disallowing new better paths to be discovered.

return G = (V, E)

 $V \leftarrow \emptyset; E \leftarrow \emptyset$

for $i = 0, \ldots, n$ do

 $q_{rand} \leftarrow \mathsf{SampleFree}$

Rapidly-exploring Random Graph (RRG)

Other Variants of the Optimal Motion Planning

Rapidly-exploring Random Graph (RRG)

 $\mathcal{Q}_{\textit{near}} \leftarrow \mathsf{Near}(\textit{G} = (\textit{V}, \textit{E}), \textit{q}_{\textit{new}}, \mathsf{min}\{\gamma_{\textit{RRG}}(\mathsf{log}(\mathsf{card}(\textit{V})) / \mathsf{card}(\textit{V}))^{1/d}, \eta\})$

 $E \leftarrow E \cup \{(q_{near}, q_{new}), (q_{new}, q_{near})\}$ // Connect Q_{near} with q_{new} .

 $V \leftarrow V \cup \{q_{new}\}; E \leftarrow E \cup \{(q_{nearest}, q_{new}), (q_{new}, q_{nearest})\}$

Proposed by Karaman and Frazzoli (2011). Theoretical results are related to properties of Rai introduced by Gilbert (1961) and further studied by Penrose (1999).

Algorithm 4: Rapidly-exploring Random Graph (RRG)

Input: q_{init} , the number of samples nOutput: G = (V, E)

 $q_{nearest} \leftarrow Nearest(G = (V, E), q_{rand})$ $q_{new} \leftarrow Steer(q_{nearest}, q_{rand})$

foreach $q_{near} \in Q_{near}$ do

if CollisionFree(q_{near}, q_{new}) then

Rapidly-exploring Random Graph (RRG)

■ PRM* follows the standard PRM algorithm where connections are attempted between roadmap vertices that are the within connection radius r as the function of n:

$$r(n) = \gamma_{PRM} (\log(n)/n)^{1/d}.$$

- RRT* is a modification of the RRG, where cycles are avoided

 - A tree roadmap allows considering non-holonomic dynamics and kinodynamic constraints.
 - It is basically the RRG with "rerouting" the tree when a better path is discovered.

Rapidly-exploring Random Graph (RRG)

RRG Expansions

- At each iteration, RRG tries to connect new sample to all vertices in the r_n ball centered
- The ball of radius

$$r(\mathsf{card}(V)) = \min \left\{ \gamma_{\mathsf{RRG}} \left(\frac{\log \left(\mathsf{card}(V) \right)}{\mathsf{card}(V)} \right)^{1/d}, \eta \right\},$$

- η is the constant of the local steering function;
- $\gamma_{RRG} > \gamma_{RRG}^* = 2(1+1/d)^{1/d} (\mu(C_{free})/\zeta_d)^{1/d};$
 - d dimension of the space;
 - $\mu(C_{\text{free}})$ Lebesgue measure of the obstacle-free space;

RRT. n=500

- ζ_d volume of the unit ball in d-dimensional Euclidean space.
- The connection radius decreases with n.
- lacktriangle The rate of decay pprox the average number of connections attempted is proportional to log(n).

Example of Solution 1/3

Rapidly-exploring Random Graph (RRG)

RRT. n=10000

Rapidly-exploring Random Graph (RRG)

RRG Properties

- Probabilistically complete;
- Asymptotically optimal;
- Complexity is O(log n).

- Computational efficiency and optimality:
 - It attempts a connection to $\Theta(\log n)$ nodes at each iteration;

Reduce volume of the "connection" ball as log(n)/n;

In average

(per one sample)

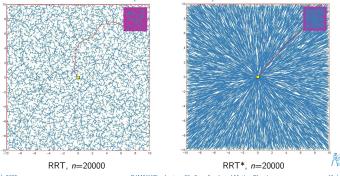

Increase the number of connections as log(n).

Improved Sampling-based Motion Planners

- Although asymptotically optimal sampling-based motion planners such as RRT* or RRG may provide high-quality or even optimal solutions to the complex problem, their performance in simple scenarios (such as 2D) is relatively poor.
- The computational performance can be improved similarly as for the RRT.
 - Using goal biasing, supporting sampling in narrow passages, multi-tree growing (Bidirectional RRT).
- The general idea of improvements is based on informing the sampling process
- Many modifications of the algorithms exists, selected representative modifications are
 - Informed RRT*:

Informed RRT

Covariant Hamiltonian Optimization for Motion Planning (CHOMP)

- Trajectory optimization based on functional gradient techniques to improve the trajectory with trade-off between trajectory smoothness and obstacle avoidance.
- Trajectory function $\pi: [0,T] \to \mathcal{C}$ with a cost function $\mathcal{U}: \Pi \to \mathbb{R}^+$

■ Smoothness cost can be defined as $\mathcal{U}_{smooth}(\pi) = \frac{1}{2} \int_0^T \|\pi'(t)\|^2 dt$.

- The trajectory optimization $\pi^* = \operatorname{argmin}_{\pi \in \Pi} \mathcal{U}(\pi)$, s.t. $\pi(0) = q_{\mathsf{init}}$ and $\pi(T) = q_{\mathsf{goal}}$.
- CHOMP instantiates functional gradient descent for the cost
 - $U(\pi) = U_{smooth}(\pi) + \lambda U_{obs}(\pi)$ (1)
- Computing the cost for each point of the trajectory, thus integral over time.

Zucker, M., Ratliff, N., Dragan, A. D., Pivtoraiko, M., Klingensmith, M., Dellin, C. M., Bagnell, J. A., and Srinivasa, S. S.: CHOMF for motion planning. The International Journal of Robotics Research. 32(9-10):1164-1193, 2013.

Obstacle cost

Refinement and repair of the search graph during the navigation (quick rewiring of the shortest path)

Motion Planning for Dynamic Environments – RRT^x

- In the previous cases, we consider existing roadmap or relatively "simple" collision free (shortest) paths in the polygonal domain.
- However, determination of the collision-free path in high dimensional configuration space (Cspace) can be a challenging problem itself.
- Therefore, we can generalize the MTP to multi-goal motion planning (MGMP) considering motion planners using the notion of C-space for avoiding collisions.
- An example of MGMP can be to plan a cost efficient trajectory for hexapod walking robot to visit a set of target locations.

RRTX - Robot in 2D

Multi-Goal Motion Planning

Multi-Goal Motion Planning

Problem Statement - MGMP Problem

- The working environment $\mathcal{W} \subset \mathbb{R}^3$ is represented as a set of obstacles $\mathcal{O} \subset \mathcal{W}$ and the robot configuration space \mathcal{C} describes all possible configurations of the robot in \mathcal{W} .
- For $q \in \mathcal{C}$, the robot body $\mathcal{A}(q)$ at q is collision free if $\mathcal{A}(q) \cap \mathcal{O} = \emptyset$ and all collision free configurations are denoted as C_{free} .
- Set of n goal locations is $\mathcal{G} = (g_1, \dots, g_n)$, $g_i \in \mathcal{C}_{free}$.
- lacktriangle Collision free path from q_{start} to q_{goal} is $\kappa:[0,1] o \mathcal{C}_{free}$ with $\kappa(0)=q_{start}$ and $d(\kappa(1), q_{end}) < \epsilon$, for an admissible distance ϵ .
- Multi-goal path τ is admissible if $\tau:[0,1]\to \mathcal{C}_{free},\ \tau(0)=\tau(1)$ and there are n points such that $0 \le t_1 \le t_2 \le ... \le t_n$, $d(\tau(t_i), v_i) < \epsilon$, and $\bigcup_{1 \le i \le n} v_i = \mathcal{G}$.
- The problem is to find the path τ^* for a cost function c such that $c(\tau^*) =$ $\min\{c(\tau) \mid \tau \text{ is admissible multi-goal path}\}$

MGMP - Existing Approches

- Determining all paths connecting any two locations g_i, g_i ∈ G is usually very computationally demanding.
- Considering Euclidean distance as an approximation in the solution of the TSP as the Minimum Spanning Tree (MST) - Edges in the MST are iteratively refined using optimal motion planner until all edges represent a feasible solution. Saha, M., Roughgarden, T., Latombe, J.-C., Sanchez-Ante, G.: Planning Tours of Robotic Arms among , International Journal of Robotics Research, 5(3):207–223, 2006

Part III

Part 3 – Multi-goal Motion Planning (MGMP)

- Synergistic Combination of Layers of Planning (SyCLoP) A combination of route and trajectory planning. Plaku, E., Kavraki, L.E., Vardi, M.Y. (2010): Motion Planning With Dynam of Layers of Planning, IEEE Transactions on Robotics, 26(3):469-482, 2010.
- Steering RRG roadmap expansion by unsupervised learning for the TSP.
- Steering PRM* expansion using VNS-based routing planning in the Physical Orienteering Problem (POP).

Summary of the Lecture

Topics Discussed – Randomized Sampling-based Methods

- Single and multi-query approaches Probabilistic Roadmap Method (PRM); Rapidly Exploring Random Tree (RRT).
- Optimal sampling-based planning Rapidly-exploring Random Graph (RRG).
- Properties of the sampling-based motion planning algorithms:
 - Path, collision-free path, feasible path;
 - Feasible path planning and optimal path planning;
 - Probabilistic completeness, strong δ-clearance, robustly feasible path planning problem;
- Asymptotic optimality, homotopy, weak δ-clearance, robust optimal solution;
 PRM, RRT, RRG, PRM*, RRT*
- Improved randomized sampling-based methods
 - Informed sampling Informed RRT*; Improving by batches of samples and reusing previous searches using Lifelong Planning A* (LPA*)
 - Improving local search strategy to improve convergence speed.
 Planning in dynamic environments RRTX.
- Multi-goal motion planning (MGMP) problems are further variants of the robotic TSP.
