

ORM and JPA 2.0

Zdeněk Kouba, Petr Křemen

What is Object-relational mapping ?

- a typical information system architecture:

- How to avoid data format transformations when interchanging data from the (OO-based) presentation layer to the data storage (RDBMS) and back ?
- How to ensure persistence in the (OO-based) business logic ?

Example – object model

- When would You stick to one of these options ?

Example – database

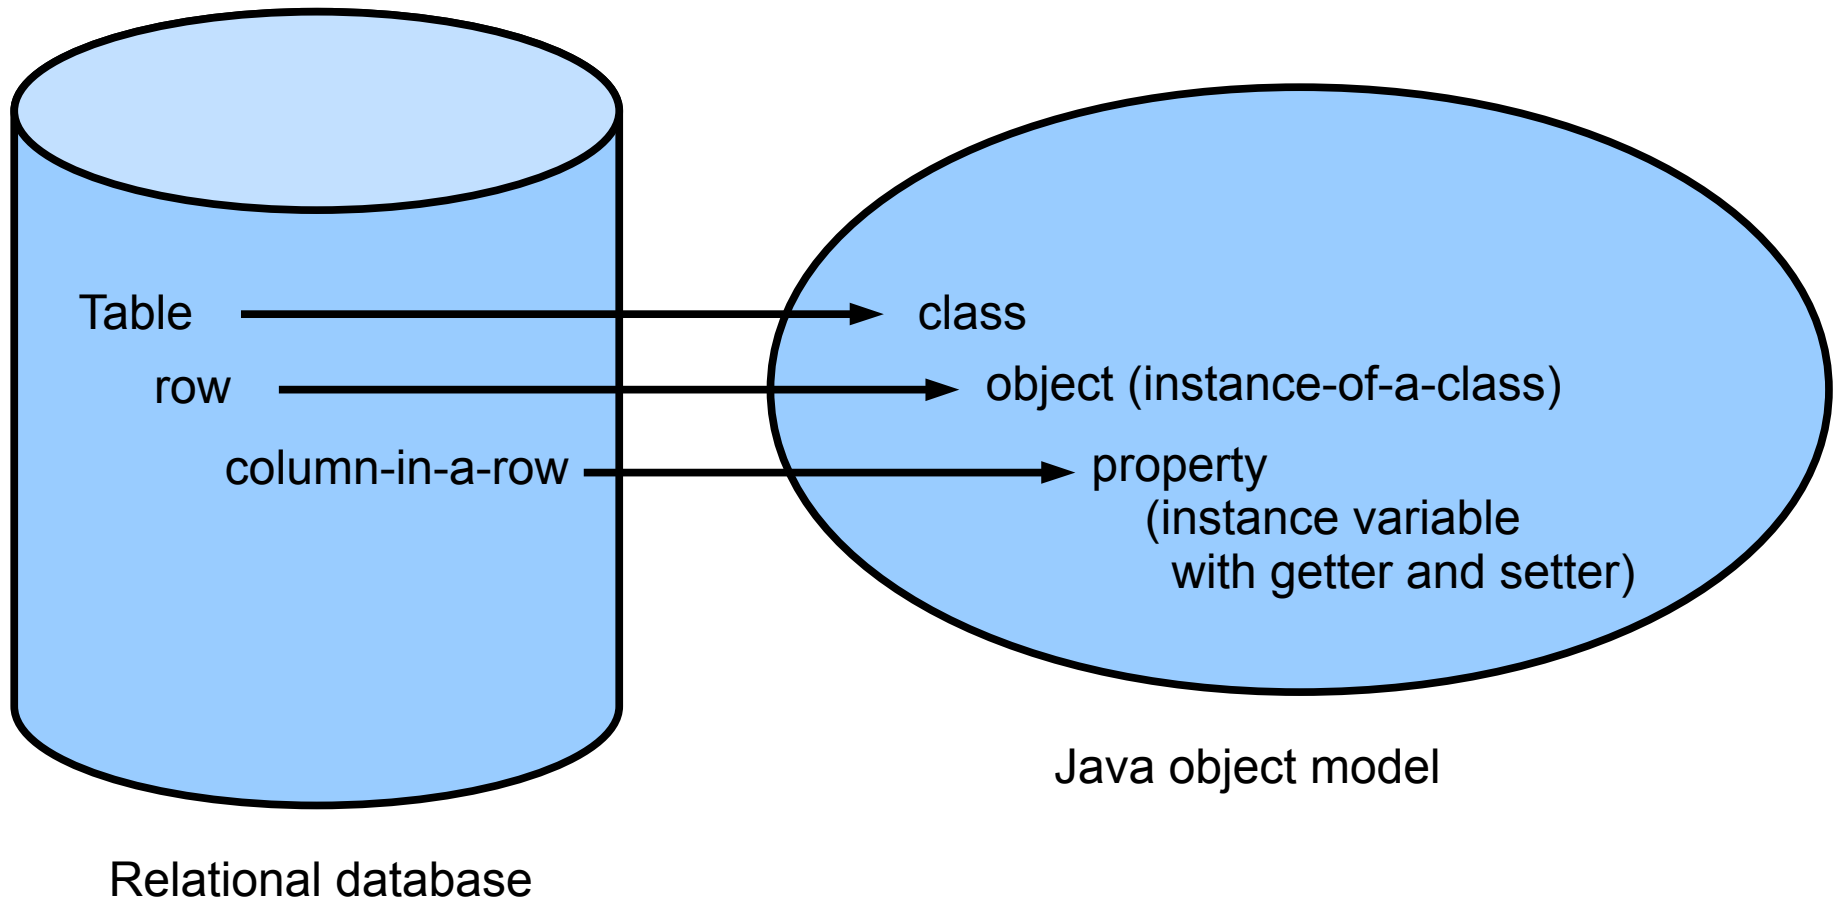

- ... and how to model it in SQL ?

Object-relational mapping

- Mapping between the database (declarative) schema and the data structures in the object-oriented language.
- Let's take a look at JPA 2.0

Object-relational mapping

JPA 2.0

- Java Persistence API 2.0 (JSR-317)
- Although part of Java EE 6 specifications, JPA 2.0 can be used both in EE and SE applications.
- Main topics covered:
 - Basic scenarios
 - Controller logic – EntityManager interface
 - ORM strategies
 - JPQL + Criteria API

JPA 2.0 – Entity Example

- Minimal example (configuration by exception):

```
@Entity
```

```
public class Person {
```

```
    @Id
```

```
    @GeneratedValue
```

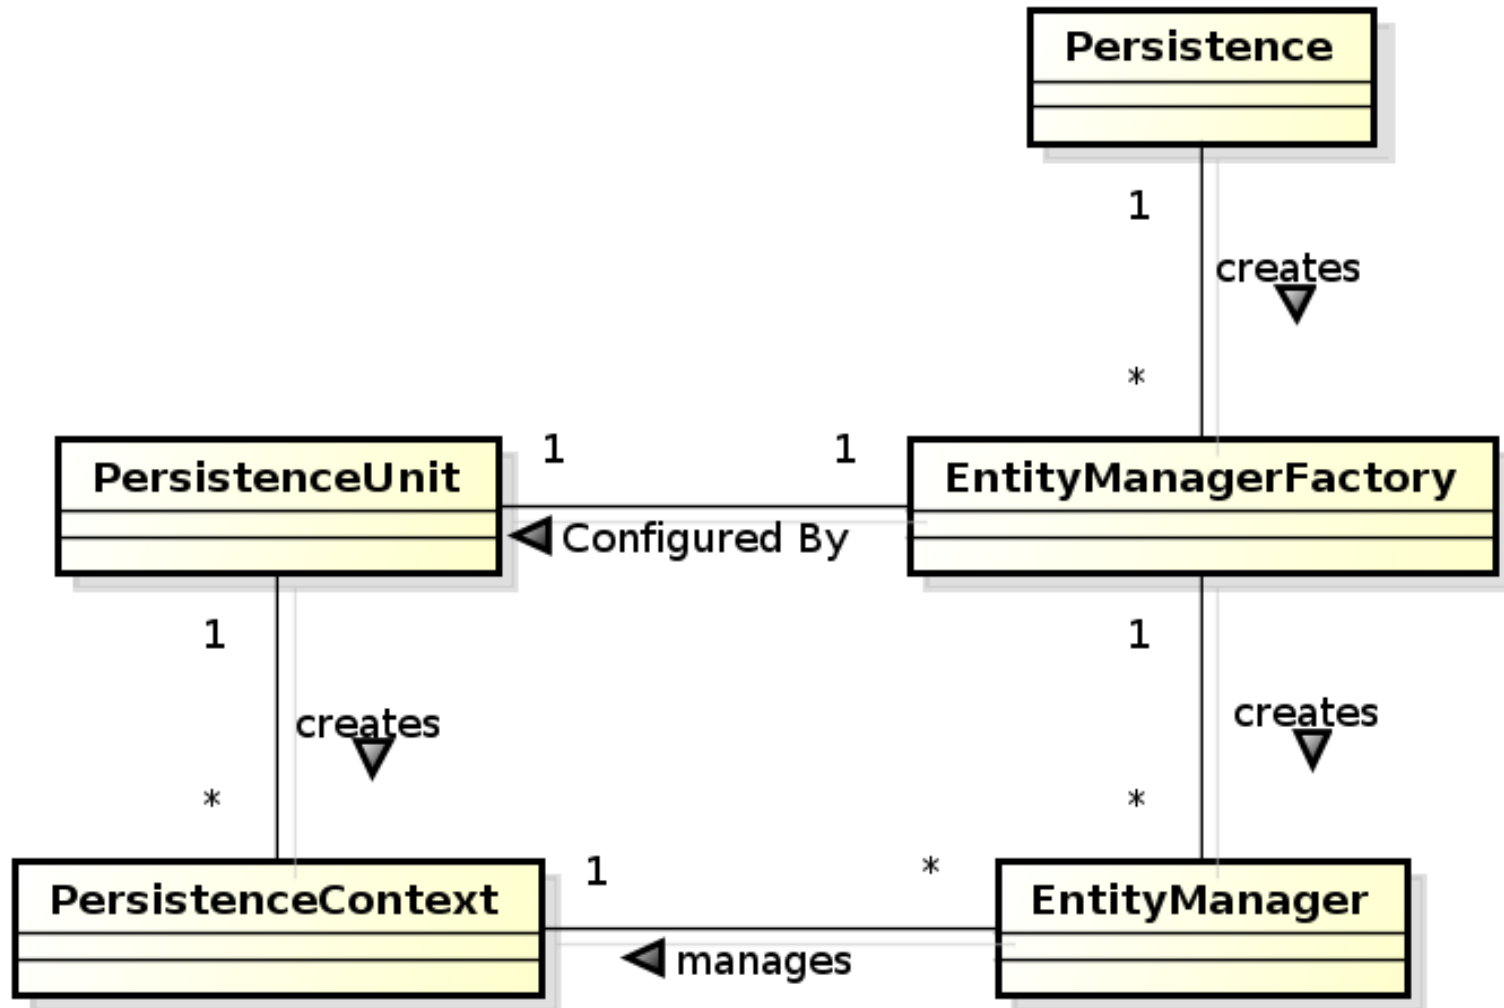

```
    private Integer id;
```

```
    private String name;
```

```
    // setters + getters
```

```
}
```

JPA2.0 – Basic concepts

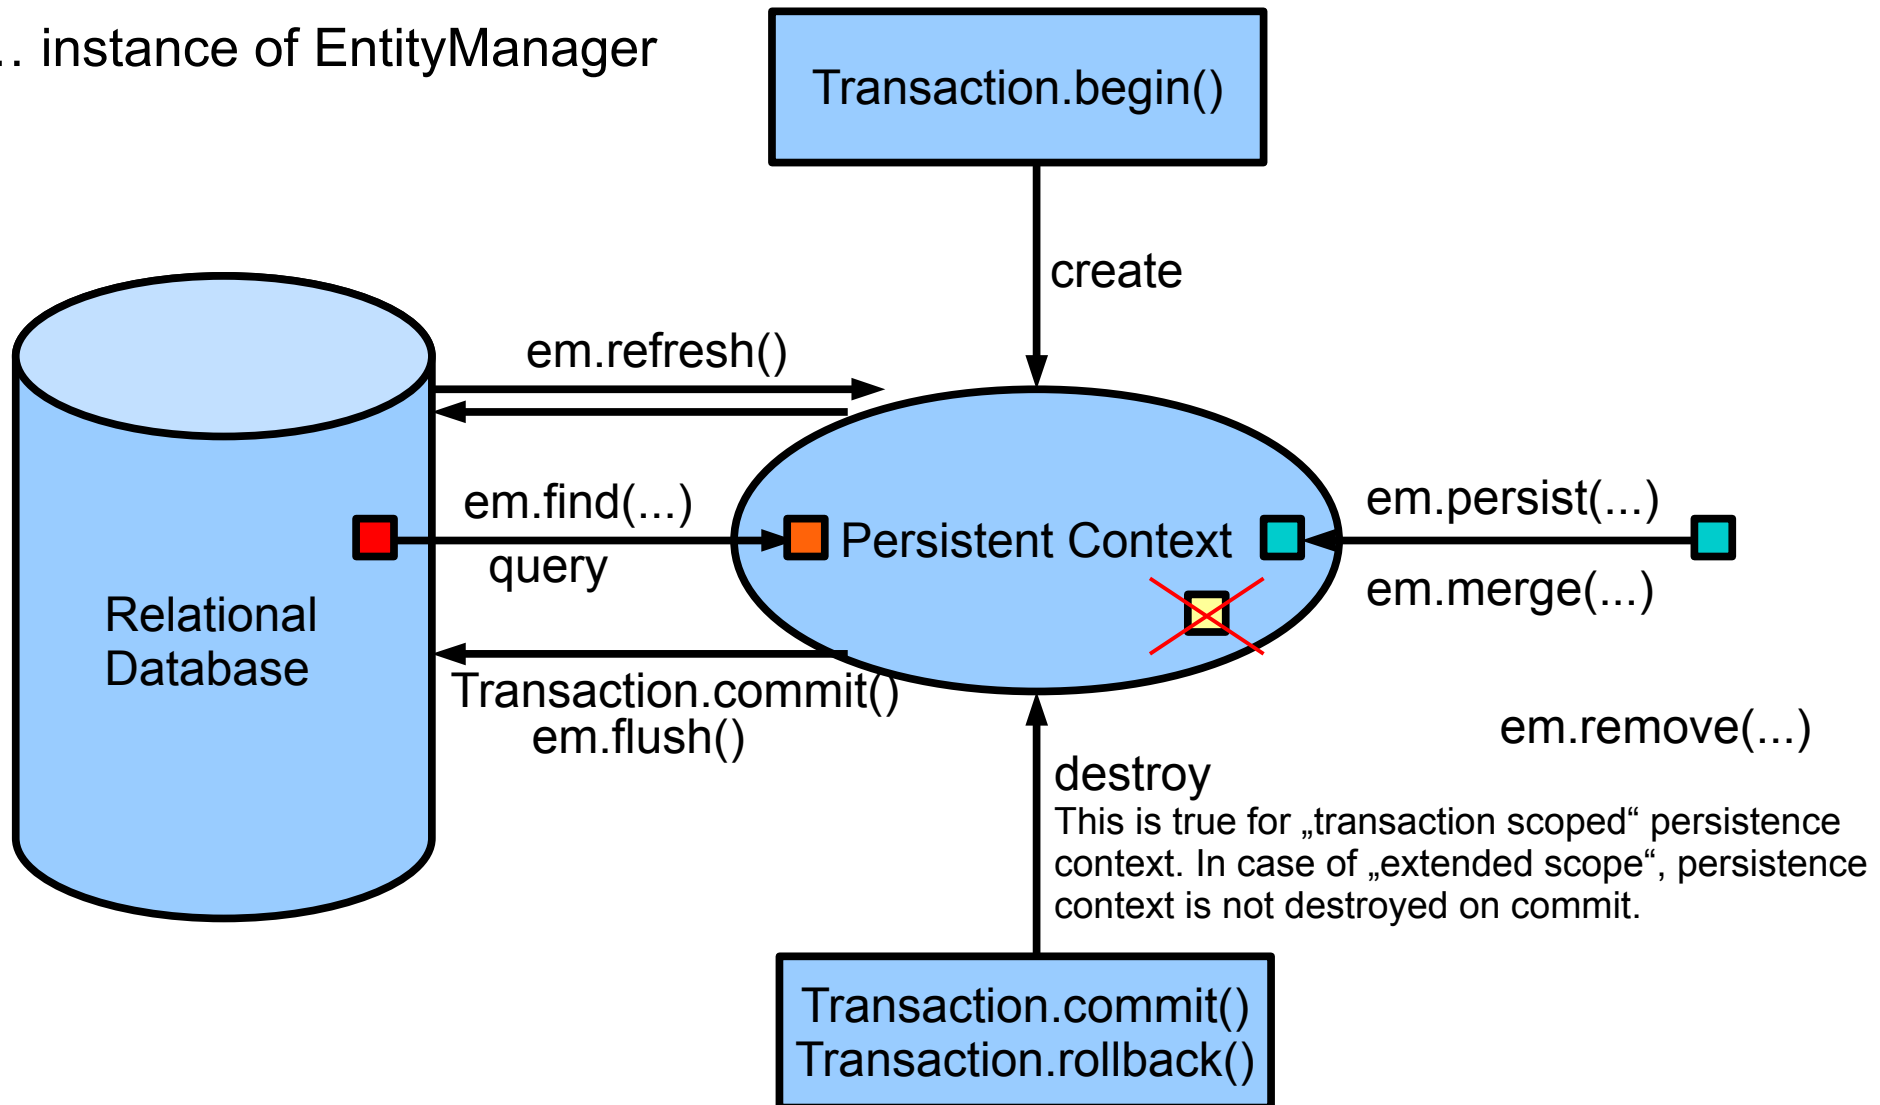

JPA 2.0 - Basics

- Let's have a set of „suitably annotated“ POJOs, called **entities**, describing your domain model.
- A set of entities is logically grouped into a **persistence unit**.
- JPA 2.0 providers :
 - generate persistence unit from existing database,
 - generate database schema from existing persistence unit.
 - TopLink (Oracle) ... JPA
 - EclipseLink (Eclipse) ... JPA 2.0
- What is the benefit of the keeping Your domain model in the persistence unit entities (OO) instead of the database schema (SQL)

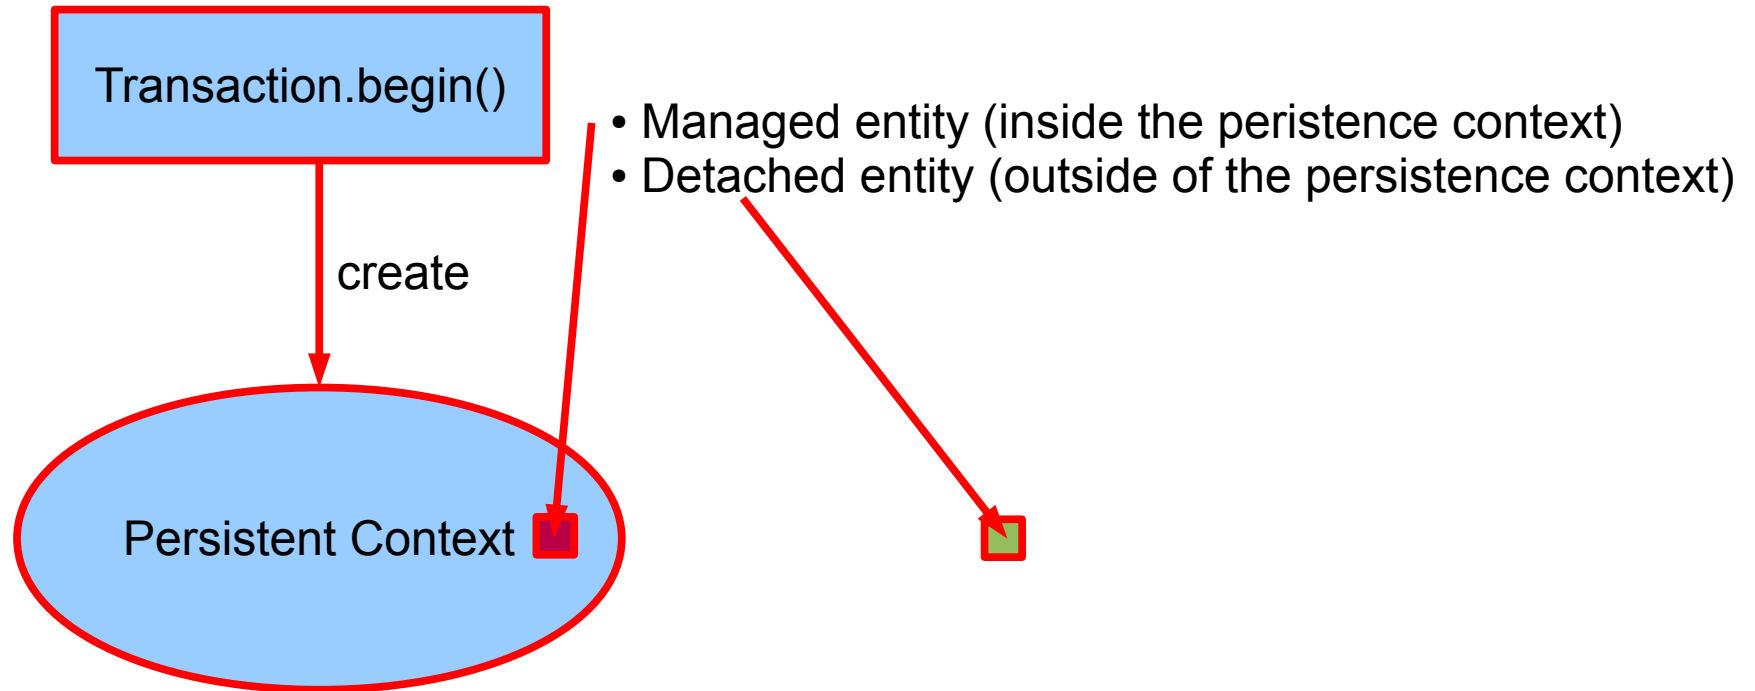

JPA 2.0 – Persistence Context

em ... instance of EntityManager

JPA 2.0 – Persistence Context

em ... instance of EntityManager

- em.persist(entity) ... persistence context must not contain an entity with the same id
- em.merge(entity) ... merging the state of an entity existing inside the persistence context and its other incarnation outside

JPA 2.0 – Persistence Context

- In runtime, the application accesses the object counterpart (represented by entity instances) of the database data. These (*managed*) entities comprise a ***persistence context (PC)***.
 - PC is synchronized with the database on demand (refresh, flush) or at transaction commit.
 - PC is accessed by an EntityManager instance and can be shared by several EntityManager instances.

JPA 2.0 – EntityManager

- **EntityManager (EM)** instance is in fact a generic DAO, while entities can be understood as DPO (managed) or DTO (detached).
- Selected operations on EM (CRUD) :
 - **Create** : em.persist(Object o)
 - **Read** : em.find(Object id), em.refresh(Object o)
 - **Update** : em.merge(Object o)
 - **Delete** : em.remove(Object o)
 - native/JPQL queries: createNativeQuery, createQuery, etc.
 - Resource-local transactions: getTransaction().
[begin(),commit(),rollback()]

ORM - Basics

- Simple View
 - Object classes = entities = SQL tables
 - Object properties (fields/accessor methods) = entity properties = SQL columns
- The ORM is realized by means of Java annotations/XML.
- Physical Schema annotations
 - @Table, @Column, @JoinColumn, @JoinTable, etc.
- Logical Schema annotations
 - @Entity, @OneToMany, @ManyToMany, etc.
- Each property can be fetched lazily/eagerly.

Access types – Field access

@Entity

```
public class Employee {  
    @Id  
    private int id;  
    ...  
    public int getId() {return id;}  
    public void setId(int id) {this.id=id;}  
    ...  
}
```

The provider will get and set the fields of the entity using reflection (not using getters and setters).

Access types – Property access

@Entity

```
public class Employee {  
    private int id;  
    ...  
    @Id  
    public int getId() {return id;}  
    public void setId(int id) {this.id=id;}  
    ...  
}
```

**Annotation is placed in front of getter.
(Annotation in front of setter abandoned)**

The provider will get and set the fields of the entity by invoking getters and setters.

Access types – Mixed access

- Field access with property access combined within the same entity hierarchy (or even within the same entity).
- `@Access` – defines the default access mode (may be overridden for the entity subclass)
- An example on the next slide

Access types – Mixed access

@Entity @Access(AccessType.FIELD)

```
public class Employee {
    public static final String LOCAL_AREA_CODE = "613";
    @Id private int id;
    @Transient private String phoneNum;
    ...
    public int getId() {return id;}
    public void setId(int id) {this.id = id;}

    public String getPhoneNumber() {return phoneNum;}
    public void setPhoneNumber(String num) {this.phoneNum=num;}

    @Access(AccessType.PROPERTY) @Column(name="PHONE")
    protected String getPhoneNumberForDb() {
        if (phoneNum.length()==10) return phoneNum;
        else return LOCAL_AREA_CODE + phoneNum;
    }
    protected void setPhoneNumberForDb(String num) {
        if (num.startsWith(LOCAL_AREA_CODE))
            phoneNum = num.substring(3);
        else phoneNum = num;
    }
}
```

ORM – Basic data types

- Primitive Java types: String → varchar/text, Integer → int, Date → TimeStamp/Time/Date, etc.
- Wrapper classes, basic type arrays, Strings, temporal types
- @Column – physical schema properties of the particular column (nullable, insertable, updatable, precise data type, defaults, etc.)
- @Lob – large objects
- Default EAGER fetching (except Lobs)

```
@Column(name="id")  
private String getName();
```

ORM – Enums, dates

- `@Enumerated(value=EnumType.String)`

`private EnumPersonType type;`

- Stored either in text column, or in int column

- `@Temporal(TemporalType.Date)`

`private java.util.Date datum;`

- Stored in respective column type according to the `TemporalType`.

ORM – Identifiers

- Single-attribute: `@Id`,
- Multiple-attribute – an identifier class must exist
 - Id. class: `@IdClass`, entity ids: `@Id`
 - Id. class: `@Embeddable`, entity id: `@EmbeddedId`
- How to write `hashCode`, `equals` for entities ?
- `@Id`

```
@GeneratedValue(strategy=GenerationType.SEQUENCE)
```

```
private int id;
```

Generated Identifiers

Strategies

- AUTO - the provider picks its own strategy
- TABLE – special table keeps the last generated values
- SEQUENCE – using the database native SEQUENCE functionality (PostgreSQL)
- IDENTITY – some DBMSs implement autonumber column

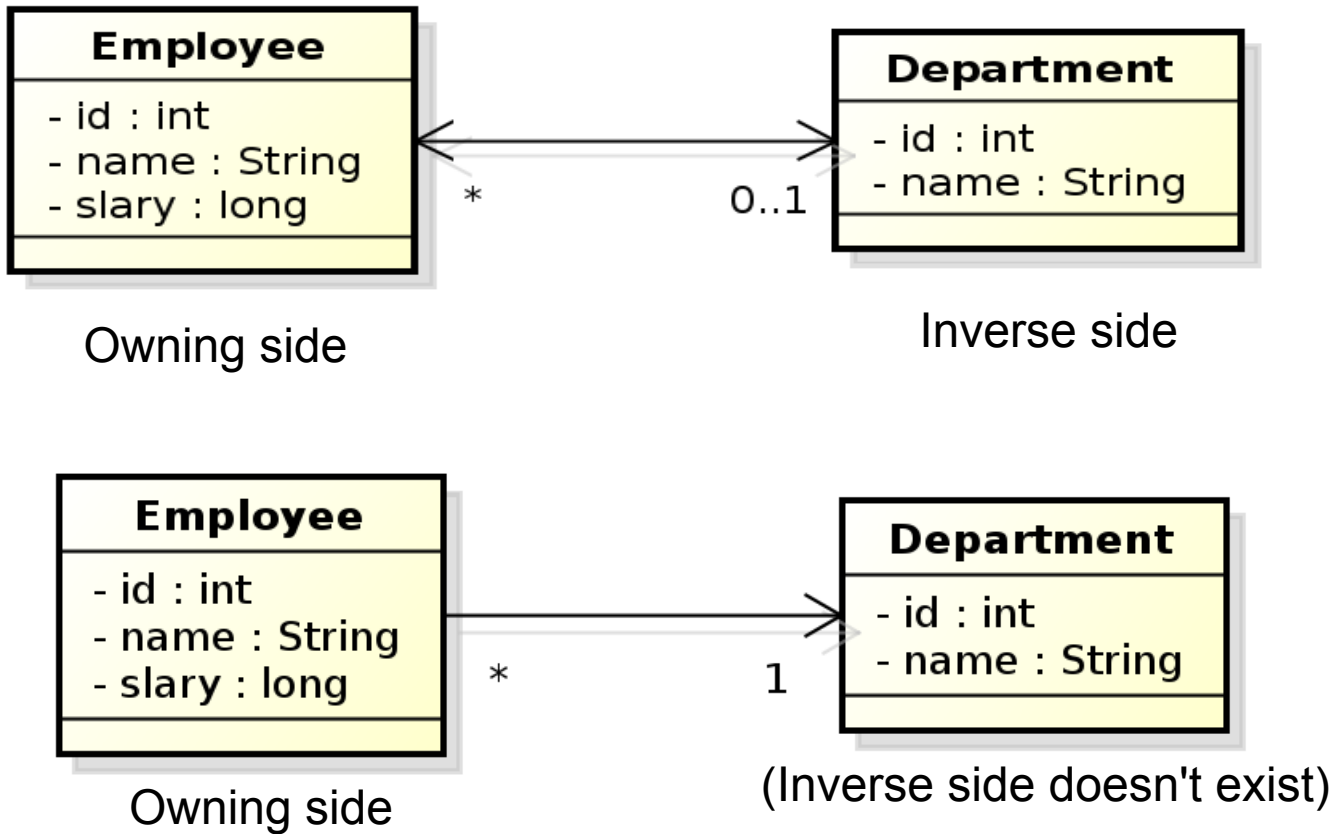

Generated Identifiers TABLE strategy

```
@TableGenerator(  
    name="AddressGen",  
    table="ID_GEN",  
    pkColumnName="GEN_NAME",  
    valueColumnName="GEN_VAL",  
    pkColumnValue="ADDR_ID",  
    initialValue=10000,  
    allocationSize=100)
```

```
@Id @GeneratedValue(generator="AddressGen")
```

```
private int id;
```

ORM – Relationships

ORM – Relationships

		unidirectional	bidirectional
many-to-one	owning	@ManyToOne [@JoinColumn]	@ManyToOne [@JoinColumn]
	inverse	X	@OneToMany(mappedBy)
one-to-many	owning	@OneToMany [@JoinTable]	@ManyToOne [@JoinColumn]
	inverse	X	@OneToMany(mappedBy)
one-to-one	owning (any)	@OneToOne [@JoinColumn]	@OneToOne [@JoinColumn]
	inverse (the other)	X	@OneToOne(mappedBy)
many-to-many	owning (any)	@ManyToMany [@JoinTable]	@ManyToMany [@JoinTable]
	inverse (the other)	X	@ManyToMany(mappedBy)

Unidirectional many-to-one relationship

Owning side

@Entity

```
public class Employee {
```

```
    // ...
```

@ManyToOne

```
    private Department department;
```

```
    // ...
```

```
}
```

In database, the N:1 relationship is implemented by means of a foreign key placed in the Employee table. In this case, the foreign key has a default name.

Unidirectional many-to-one relationship

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    @ManyToOne
```

```
    @JoinColumn(name="DEPT_ID")
```

```
    private Department department;
```

In this case, the foreignkey is defined my means of the @JoinColumn annotation.

Bidirectional many-to-one relationship

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    @ManyToOne
```

```
    @JoinColumn(name="DEPT_ID")
```

```
    private Department department;
```

```
}
```

@Entity

```
public class Department {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    @OneToMany(mappedBy="department")
```

```
    private Collection<Employee> employees;
```

```
}
```

Unidirectional one-to-one relationship

Owning side

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String Name;
```

```
    @OneToOne
```

```
    @JoinColumn(name="PSPACE_ID")
```

```
    private ParkingSpace parkingSpace;
```

```
}
```

Bidirectional one-to-one relationship

```
@Entity
public class Employee {
```

```
    @Id private int id;
    private String Name;
    @OneToOne
    @JoinColumn(name="PSPACE_ID")
    private ParkingSpace parkingSpace;
```

```
@Entity
public class ParkingSpace {
```

```
    @Id private int id;
    private int lot;
    private String location;
    @OneToOne(mappedBy="parkingSpace");
    private Employee employee;
```

Bidirectional many-to-many relationship

```
@Entity
public class Employee {
```

```
    @Id private int id;
    private String Name;
    @ManyToMany
    private Collection<Project> projects;
```

```
}
```

```
@Entity
public class Project {
```

```
    @Id private int id;
    private String name;
    @ManyToMany(mappedBy="projects");
    private Collection<Employee> employees;
```

```
}
```

In database, N:M relationship must be implemented by means of a table with two foreign keys. In this case, both the table and its columns have default names.

Bidirectional many-to-many relationship

```
@Entity
public class Employee {

    @Id private int id;
    private String Name;
    @ManyToMany
    @JoinTable(name="EMP_PROJ",
        joinColumns=@JoinColumn(name="EMP_ID"),
        inverseJoinColumns=@JoinColumn(name="PROJ_ID"))
    private Collection<Project> project;

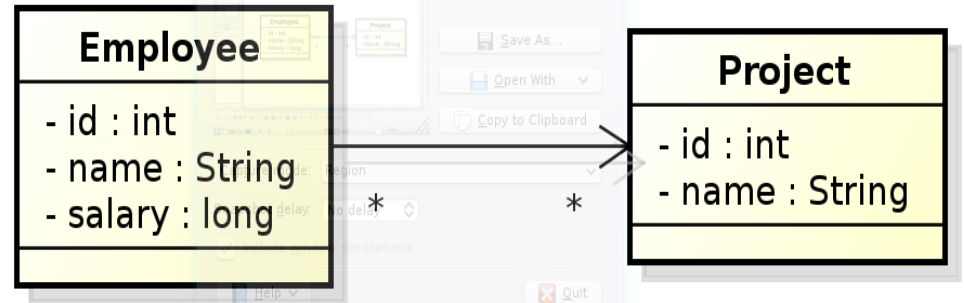

}
```

```
@Entity
public class Project {

    @Id private int id;
    private String name;
    @ManyToMany(mappedBy="projects");
    private Collection<Employee> employees;

}
```

Unidirectional many-to-many relationship

Owning side

```
@Entity
public class Employee {

    @Id private int id;
    private String Name;
    @ManyToMany
    @JoinTable(name="EMP_PROJ",
        joinColumns=@JoinColumn(name="EMP_ID"),
        inverseJoinColumns=@JoinColumn(name="PROJ_ID"))
    private Collection<Project> project;

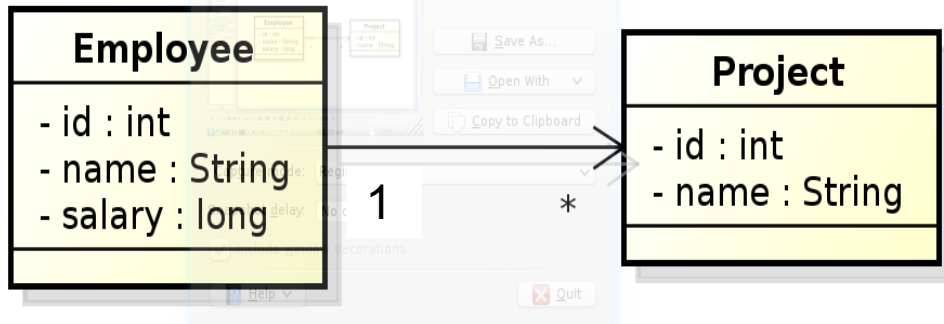

}
```

```
@Entity
public class Project {

    @Id private int id;
    private String name;

}
```

Unidirectional one-to-many relationship

Owning side

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    @OneToMany
```

```
    @JoinTable(name="EMP_PROJ",
```

```
        joinColumns=@JoinColumn(name="EMP_ID"),
```

```
        inverseJoinColumns=@JoinColumn(name="PROJ_ID"))
```

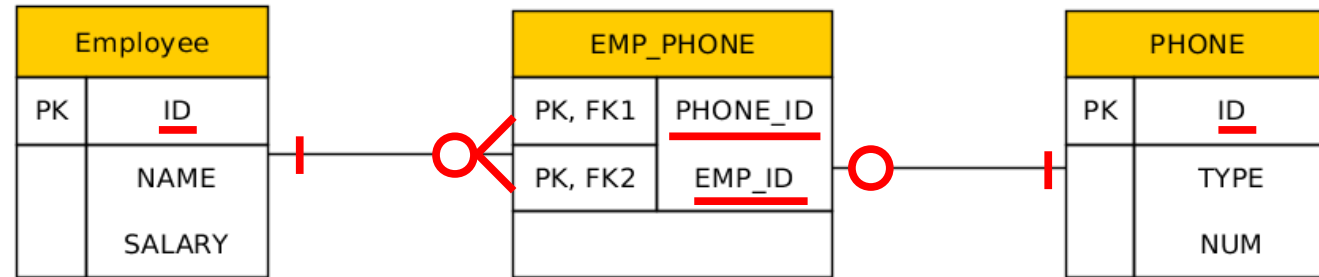

```
    private Collection<Project> projects;
```

```
}
```

Unidirectional one-to-many relationship

Owning side

Logical database schema

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    private float salary;
```

```
    @OneToMany
```

```
    @JoinTable(name="EMP_PHONE",
```

```
        joinColumns=@JoinColumn(name="EMP_ID"),
```

```
        inverseJoinColumns=@JoinColumn(name="PHONE_ID"))
```

```
    private Collection<Project> phones;
```

```
}
```

Lazy Relationships

```
@Entity
public class Employee {

    @Id private int id;
    private String name;
    @OneToOne(fetch=FetchType.LAZY)
    private ParkingSpace parkingSpace;

}
```

Embedded Objects

EMPLOYEE	
PK	ID
	NAME
	SALARY
	STREET
	CITY
	STATE
	ZIP_CODE

@Embeddable

@Access(AccessType.FIELD)

```

public class Address {
    private String street;
    private String city;
    private String state;
    @Column(name="ZIP_CODE")
    private String zip;
}
    
```

@Entity

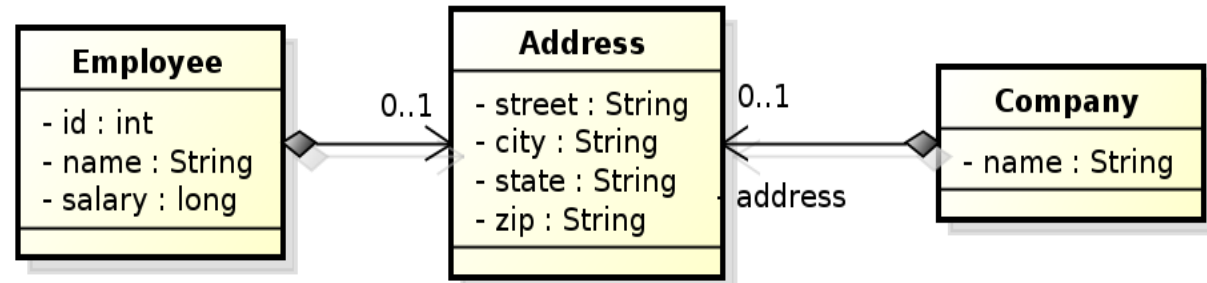

```

public class Employee {
    @Id private int id;
    private String name;
    private long salary;
    @Embedded private Address address;
}
    
```

Embedded Objects

EMPLOYEE	
PK	ID
	NAME
	SALARY
	STREET
	CITY
	PROVINCE
	POSTAL_CODE

COMPANY	
PK	NAME
	STREET
	CITY
	STATE
	ZIP_CODE

@Embeddable

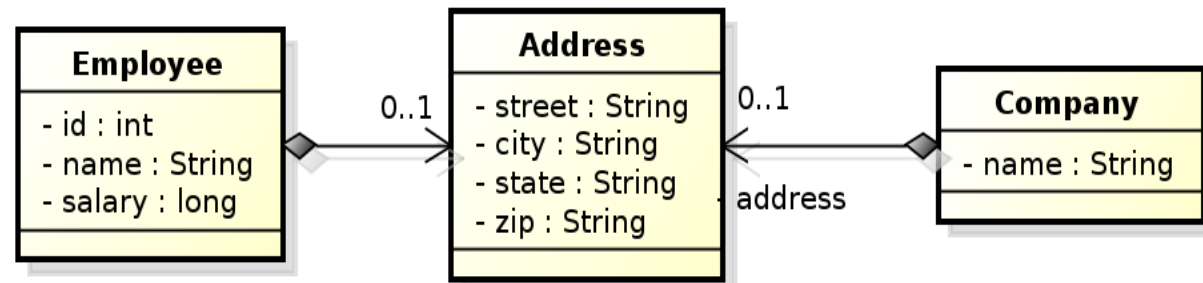

@Access(AccessType.FIELD)

```
public class Address {
    private String street;
    private String city;
    private String state;
    @Column(name="ZIP_CODE")
    private String zip;
}
```

Embedded Objects

EMPLOYEE	
PK	ID
	NAME
	SALARY
	STREET
	CITY
	PROVINCE
	POSTAL_CODE

COMPANY	
PK	NAME
	STREET
	CITY
	STATE
	ZIP_CODE

@Entity

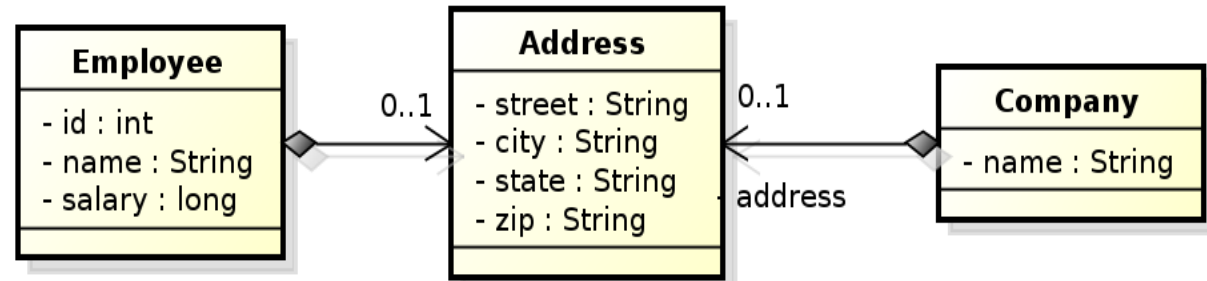

```

public class Employee {
    @Id private int id;
    private String name;
    private long salary;
    @Embedded
    @AttributeOverrides({
        @AttributeOverride(name="state", column=@Column(name="PROVINCE")),
        @AttributeOverride(name="zip", column=@Column(name="POSTAL_CODE"))
    })
    private Address address;
}
  
```

Embedded Objects

EMPLOYEE	
PK	ID
	NAME
	SALARY
	STREET
	CITY
	PROVINCE
	POSTAL_CODE

COMPANY	
PK	NAME
	STREET
	CITY
	STATE
	ZIP_CODE

@Entity

```
public class Company {
    @Id private String name;
    @Embedded
    private Address address;
}
```

Cascade Persist

```
@Entity
public class Employee {
    // ...
    @ManyToOne(cascade=cascadeType.PERSIST)
    Address address;
    // ...
}
```

```
Employee emp = new Employee();
emp.setId(2);
emp.setName("Rob");
Address addr = new Address();
addr.setStreet("164 Brown Deer Road");
addr.setCity("Milwaukee");
addr.setState("WI");
emp.setAddress(addr);
em.persist(addr);
em.persist(emp);
```

Persisting bidirectional relationship

```
...
Department dept = em.find(Department.class, 101);
Employee emp = new Employee();
emp.setId(2);
emp.setName("Rob");
emp.setSalary(25000);
dept.employees.add(emp); // @ManyToOne(cascade=cascadeType.PERSIST)
em.persist(emp);
!!! emp.departments still doesn't contain dept !!!

em.refresh(dept);

!!! emp.departments does contain dept now !!!
```

Cascade

List of operations supporting cascading:

- `cascadeType.ALL`
- `cascadeType.DETACH`
- `cascadeType.MERGE`
- `cascadeType.PERSIST`
- `cascadeType.REFRESH`
- `cascadeType.REMOVE`

Collection Mapping

- Collection-valued relationship (above)
 - @OneToMany
 - @ManyToMany
- Element collections
 - @ElementCollection
 - Collections of Embeddable (new in JPA 2.0)
 - Collections of basic types (new in JPA 2.0)

- Specific types of Collections are supported
 - Lists
 - Maps

Collection Mapping

Cited from:

<http://mdshannan1.blogspot.cz/2010/09/jpa-2-new-feature-elementcollection.html>

JPA 2 new feature @ElementCollection explained

@ElementCollection is new annotation introduced in JPA 2.0

This will help us get rid of One-Many and Many-One shitty syntax.

Příklad:

```
@ElementCollection  
private List<String> certifications = new ArrayList<String>();
```

Collection Mapping

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    private long salary;
```

```
    // ...
```

```
    @ElementCollection(targetClass=VacationEntry.class);
```

```
    private Collection vacationBookings;
```

```
    @ElementCollection
```

```
    private Set<String> nickName;
```

```
    // ...
```

```
}
```

```
@Embeddable
```

```
public class VacationEntry {
```

```
    @Temporal(TemporalType.DATE)
```

```
    private Calendar startDate;
```

```
    @Column(name="DAYS")
```

```
    private int daysTaken;
```

```
    // ...
```

```
KBSS 2010 }
```

Collection Mapping

@Entity

```
public class Employee {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    private long salary;
```

```
    // ...
```

```
    @ElementCollection(targetClass=VacationEntry.class);
```

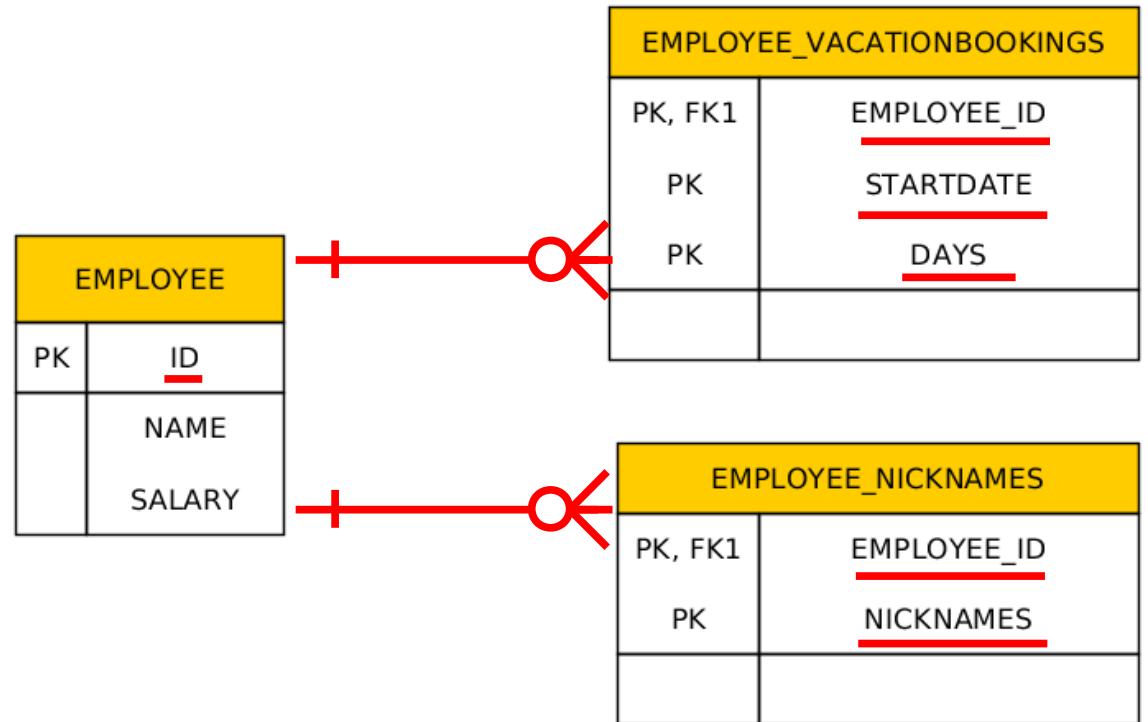

```
    private Collection vacationBookings;
```

```
    @ElementCollection
```

```
    private Set<String> nickName;
```

```
    // ...
```

```
}
```

Collection Mapping

@Entity

```
public class Employee {  
    @Id private int id;  
    private String name;  
    private long salary;  
    // ...
```

```
@ElementCollection(targetClass=VacationEntry.class);
```

```
@CollectionTable(  
    name="VACATION",
```

```
    joinColumn=@JoinColumn(name="EMP_ID");
```

```
    @AttributeOverride(name="daysTaken", column="DAYS_ABS"))
```

```
private Collection vacationBookings;
```

```
@ElementCollection
```

```
    @Column(name="NICKNAME")
```

```
private Set<String> nickName;
```

```
// ...
```

```
}
```

```
@Embeddable
```

```
public class VacationEntry {
```

```
    @Temporal(TemporalType.DATE)
```

```
private Calendar startDate;
```

```
    @Column(name="DAYS")
```

```
private int daysTaken;
```

```
// ...
```

```
}
```

Collection Mapping

```

@Entity
public class Employee {
    @Id private int id;
    private String name;
    private long salary;
    // ...
    @ElementCollection(targetClass=VacationEntry.class);
    @CollectionTable(
        name="VACATION",
        joinColumn=@JoinColumn(name="EMP_ID");
    @AttributeOverride(name="daysTaken", column="DAYS_ABS"))
    private Collection vacationBookings;

```

```

@ElementCollection
    @Column(name="NICKNAME")
    private Set<String> nickName;
    // ...
}

```

```

@Embeddable
public class VacationEntry {
    @Temporal(TemporalType.DATE)
    private Calendar startDate;

```

```

    @Column(name="DAYS")
    private int daysTaken;
    // ...
}

```

Collection Mapping

Interfaces:

- Collection may be used for mapping purposes.
- Set
- List
- Map

An instance of an appropriate implementation class (HashSet, OrderedList, etc.) will be used to implement the respective property initially (the entity will be **unmanaged**).

As soon as such an Entity becomes **managed** (by calling `em.persist(...)`), we can expect to get an instance of the respective interface, not an instance of that particular implementation class when we get it back (`em.find(..)`) to the persistence context. The reason is that the JPA provider may replace the initial concrete instance with an alternate instance of the respective interface (Collection, Set, List, Map).

Collection Mapping – ordered List

- Ordering by Entity or Element Attribute
ordering according to the state that exists in each entity or element in the List
- Persistently ordered lists
the ordering is persisted by means of an additional database column(s)
typical example – ordering = the order in which the entities were persisted

Collection Mapping – ordered List

(Ordering by Entity or Element Attribute)

@Entity

```
public class Department {
```

```
    // ...
```

```
    @OneToMany(mappedBy="department")
```

```
    @OrderBy("name ASC")
```

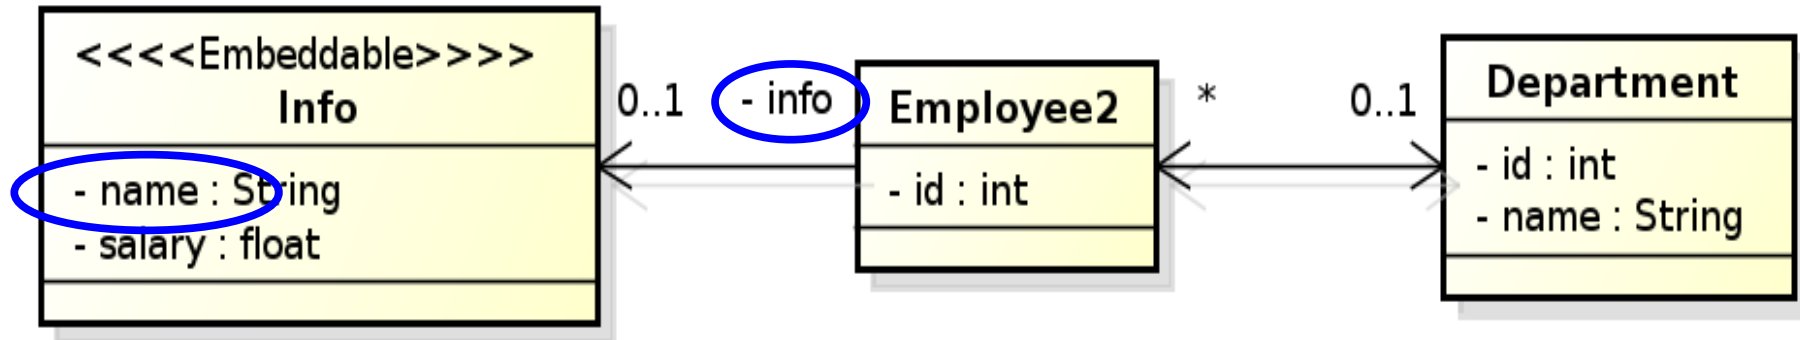

```
    private List<Employee> employees;
```

```
    // ...
```

```
}
```

Collection Mapping – ordered List

(Ordering by Entity or Element Attribute)

@Entity

```
public class Department {
```

```
    // ...
```

```
    @OneToMany(mappedBy="department")
```

```
    @OrderBy("info.name ASC")
```

```
    private List<Employee2> employees;
```

```
    // ...
```

```
}
```

Collection Mapping – ordered List

(Persistently ordered lists)

@Entity

```
public class PrintQueue {
    @Id private String name;
    // ...
    @OneToMany(mappedBy="queue")
    @OrderColumn(name="PRINT_ORDER")
    private List<PrintJob> jobs;
    // ...
}
```

Collection Mapping – ordered List

(Persistently ordered lists)

@Entity

```
public class PrintQueue {  
    @Id private String name;  
    // ...  
    @OneToMany(mappedBy="queue")  
    @OrderColumn(name="PRINT_ORDER")  
    private List<PrintJob> jobs;  
    // ...  
}
```

This annotation need not be necessarily on the owning side

Collection Mapping – Maps

Map is an object that maps keys to values.

A map cannot contain duplicate keys;

each key can map to at most one value.

Keys:

- Basic types (stored directly in the table being referred to)
 - Target entity table
 - Join table
 - Collection table
- Embeddable types (- “ -)
- Entities (only foreign key is stored in the table)

Values:

- Values are entities => Map must be mapped as a one-to-many or many-to-many relationship
- Values are basic types or embeddable types => Map is mapped as an element collection

Collection Mapping – Maps

(keying by basic type – key is String)

@Entity

```
public class Employee {  
    @Id private int id;  
    private String name;  
    private long salary;
```

@ElementCollection

@CollectionTable(name="EMP_PHONE")

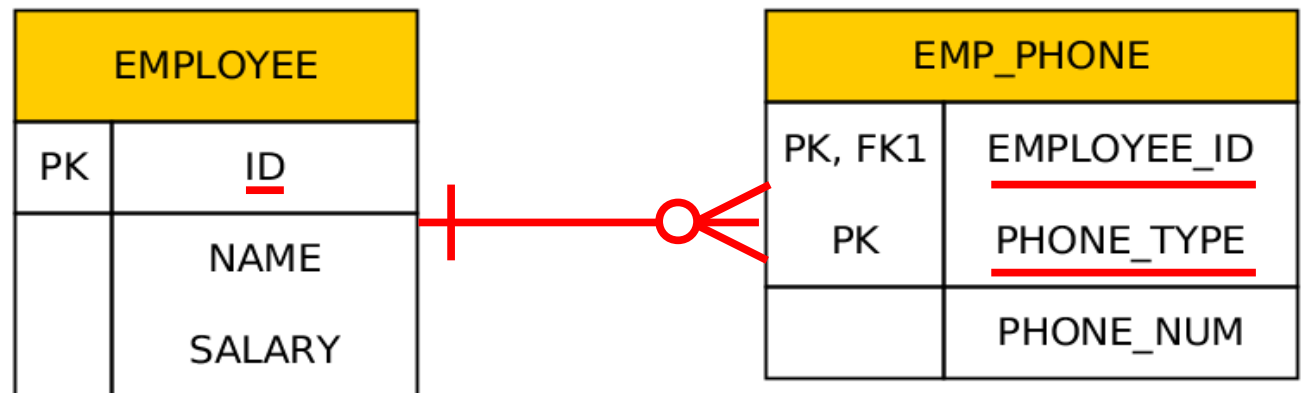

@MapKeyColumn(name="PHONE_TYPE")

@Column(name="PHONE_NUM")

private Map<String, String> phoneNumbers;

// ...

}

Collection Mapping – Maps

(keying by basic type – key is an enumeration)

@Entity

```
public class Employee {  
    @Id private int id;  
    private String name;  
    private long salary;
```

```
Public enum PhoneType {  
    Home,  
    Mobile,  
    Work  
}
```

@ElementCollection

@CollectionTable(name="EMP_PHONE")

@MapKeyEnumerated(EnumType.String)

@MapKeyColumn(name="PHONE_TYPE")

@Column(name="PHONE_NUM")

private Map<PhoneType, String> phoneNumbers;

// ...

}

Collection Mapping – Maps

(keying by basic type – 1:N relationship using a Map with String key)

@Entity

```
public class Department {
```

```
    @Id private int id;
```

```
    private String name;
```

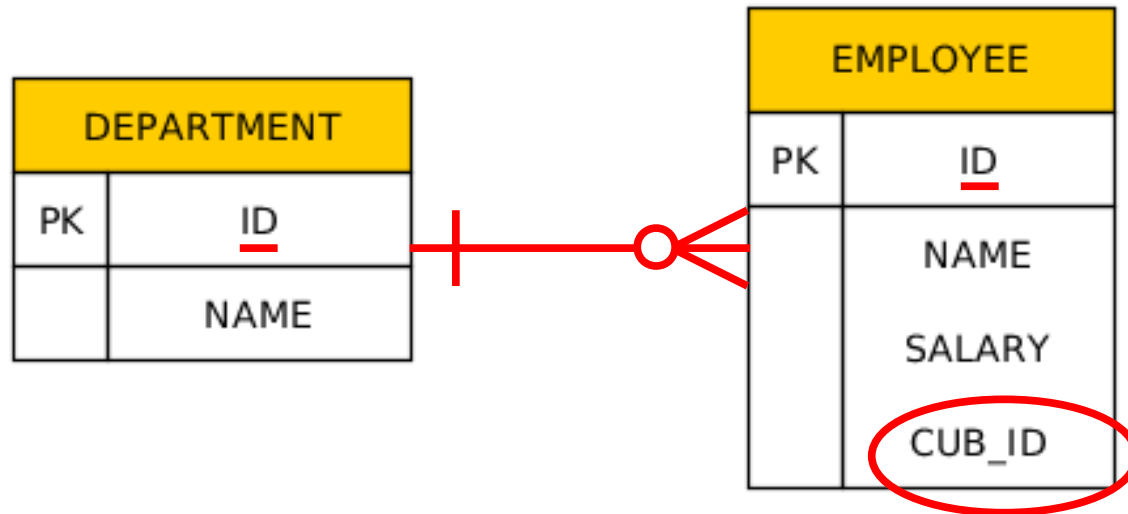

```
    @OneToMany(mappedBy="department")
```

```
    @MapKeyColumn(name="CUB_ID")
```

```
    private Map<String, Employee> employeesByCubicle;
```

```
    // ...
```

```
}
```

Collection Mapping – Maps

(keying by basic type – N:M relationship using a Map with String key)

@Entity

```
public class Department {
```

```
    @Id private int id;
```

```
    private String name;
```

```
    @ManyToMany
```

```
    @JoinTable(name="DEPT_EMP",
```

```
        joinColumns=@JoinColumn(name="DEPT_ID"),
```

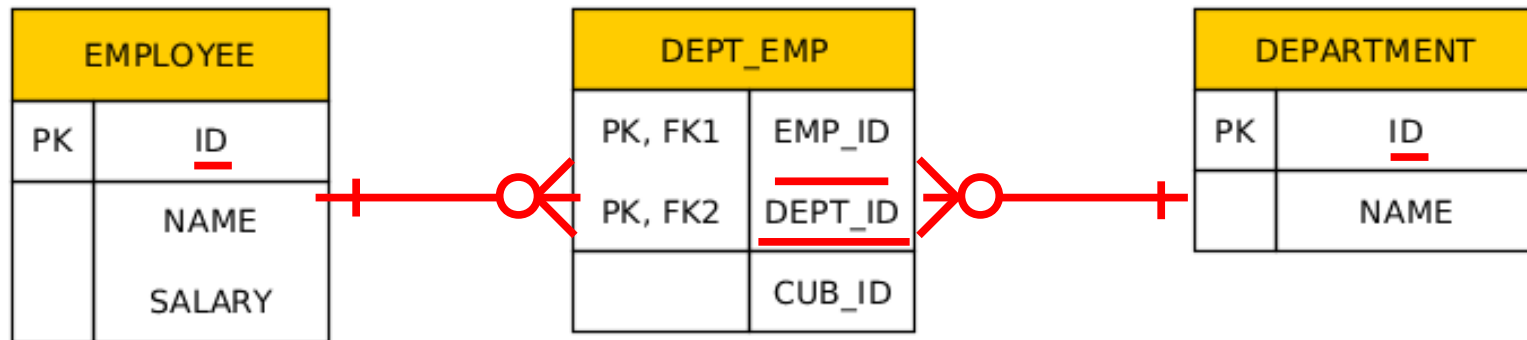

```
        inverseJoinColumns=@JoinColumn(name="EMP_ID"))
```

```
    @MapKeyColumn(name="CUB_ID")
```

```
    private Map<String, Employee> employeesByCubicle;
```

```
// ...
```

```
}
```

Collection Mapping – Maps

(keying by entity attribute)

```
@Entity
public class Department {
    // ...
    @OneToMany(mappedBy="department")
    @MapKey(name="id")
    private Map<Integer, Employee> employees;
    // ...
}
```

Collection Mapping – Maps

(keying by embeddable type)

```
@Entity
Public class Employee {
    @Id private int id;
    @Column(name="F_NAME");
    private String firstName;
    @Column(name="L_NAME");
    private String lastName;
    private long salary;
    //...
}
```

Sharing columns =>
insertable=false and
updateable = false

```
@Embeddable
public class EmployeeName {
    @Column(name="F_NAME", insertable=false,
            updateable=false)
    private String first_Name;
    @Column(name="L_NAME", insertable=false,
            updateable=false)
    private String last_Name;
    // ...
}
```

```
@Entity
public class Department {
    // ...
    @OneToMany(mappedBy="department")
    @MapKey(name="id")
    private Map<EmployeeName, Employee> employees;
    // ...
}
```

Collection Mapping – Maps

(keying by embeddable type)

```
@Entity
Public class Employee {
    @Id private int id;

    @Embedded
    private EmployeeName name;
    private long salary;
    //...
}
```

```
@Embeddable
Public class EmployeeName {
    @Column(name="F_NAME",insertable=false,
            updateable=false)
    Private String first_Name;
    @Column(name="L_NAME",insertable=false,
            updateable=false)
    Private String last_Name;
    // ...
}
```

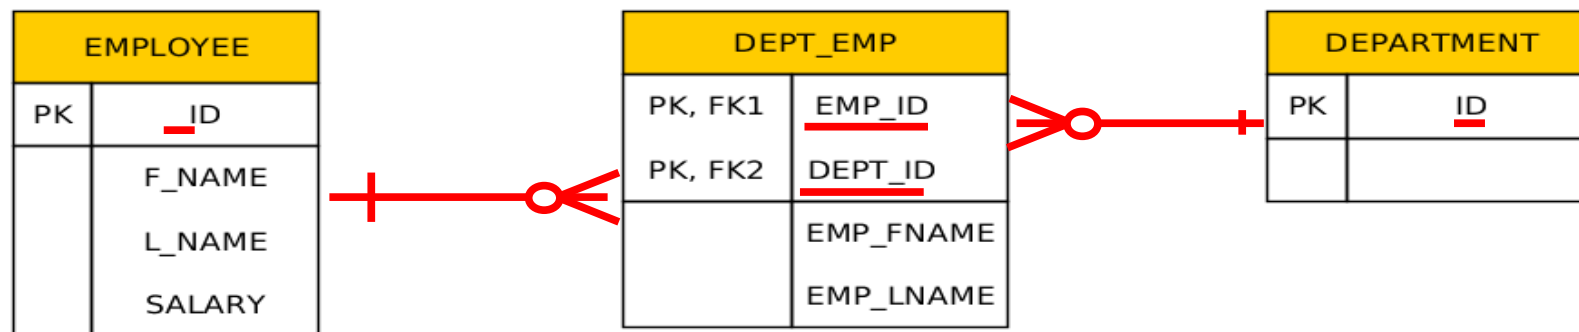

```
@Entity
public class Department {
    // ...
    @OneToMany(mappedBy="department")
    @MapKey(name="id")
    private Map<EmployeeName, Employee> employees;
    // ...
}
```

Columns are not shared

Collection Mapping – Maps

(keying by embeddable type)

```
@Entity
public class Department {
    @Id private int id;
    @ManyToMany
    @JoinTable(name="DEPT_EMP",
        joinColumns=@JoinColumn(name="DEPT_ID"),
        inverseJoinColumns=@JoinColumn(name="EMP_ID"))
    @AttributeOverrides({
        @AttributeOverride(
            name="first_Name",
            column=@Column(name="EMP_FNAME")),
        @AttributeOverride(
            name="last_Name",
            column=@Column(name="EMP_LNAME"))
    })
    private Map<EmployeeName, Employee> employees;
    // ...
}
```

Collection Mapping – Maps

(keying by embeddable type)

```
@Entity
public class Department {
    @Id private int id;
    @ManyToOne
    @JoinTable(name="DEPT_EMP",
        joinColumns=@JoinColumn(name="DEPT_ID"),
        inverseJoinColumns=@JoinColumn(name="EMP_ID"))
    @AttributeOverrides({
        @AttributeOverride(
            name="first_Name",
            column=@Column(name="EMP_FNAME")),
        @AttributeOverride(
            name="last_Name",
            column=@Column(name="EMP_LNAME"))
    })
    private Map<EmployeeName, Employee> employees;
    // ...
}
```

Collection Mapping – Maps

(keying by embeddable type)

We have to distinguish, if we are overriding embeddable attributes of the key or the value.

```
@Entity
public class Department {
    @Id private int id;
    @AttributeOverrides({
        @AttributeOverride(name="key.first_Name",
            column=@Column(name="EMP_FNAME")),
        @AttributeOverride(name="key.last_Name",
            column=@Column(name="EMP_LNAME"))
    })
    private Map<EmployeeName, EmployeeInfo> employees;
    // ...
}
```

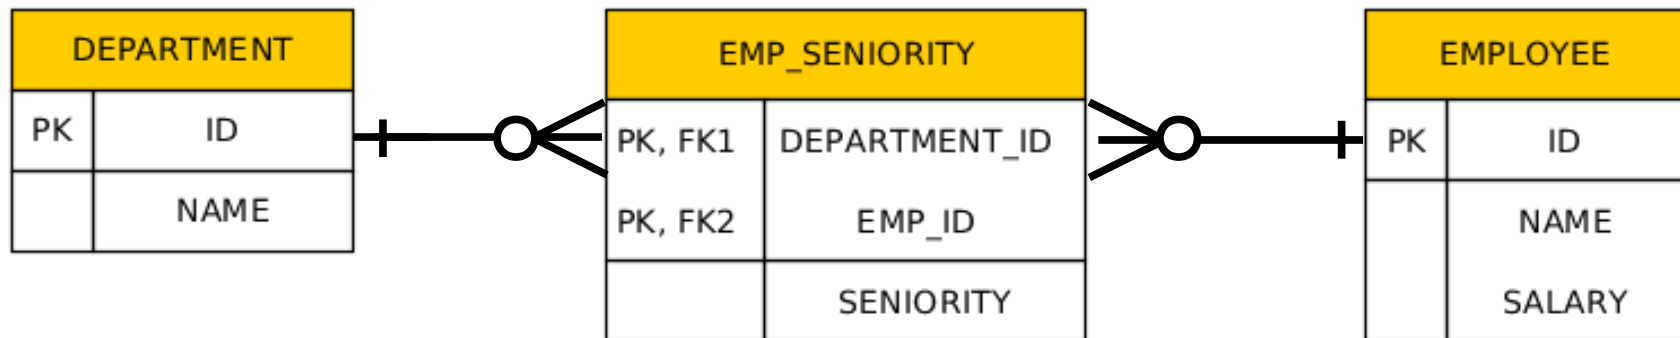

The embeddable attributes will be stored in the collection table (rather than in a join table As it was on the previous slide).

Collection Mapping – Maps

(keying by entity)

```
@Entity
public class Department {
    @Id private int id;
    private String name;
    // ...
    @ElementCollection
    @CollectionTable(name="EMP_SENIORITY")
    @MapKeyJoinColumn(name="EMP_ID")
    @Column(name="SENIORITY")
    private Map<Employee, Integer> employees;
    // ...
}
```

Collection table

Compound primary keys

Id Class

EMPLOYEE	
PK	<u>COUNTRY</u>
PK	<u>EMP_ID</u>
	NAME
	SALARY

No setters. Once created, can not be changed.

```
@Entity
@IdClass(EmployeeId.class)
public class Employee {
    @Id private String country;
    @Id
    @Column(name="EMP_ID")
    private int id;
    private String name;
    private long salary;
    // ...
}
```

```
public class EmployeeId
    implements Serializable {
    private String country;
    private int id;

    public EmployeeId() {}
    public EmployeeId(String country,
        int id) {
        this.country = country;
        this.id = id;
    }

    public String getCountry() {...};
    public int getId() {...}

    public boolean equals(Object o) {...}

    public int hashCode() {
```

```
EmployeeId id = new EmployeeId(country, id);
Employee emp = em.find(Employee.class, id);
```

Compound primary keys

Embedded Id Class

EMPLOYEE	
PK	<u>COUNTRY</u>
PK	<u>EMP_ID</u>
	NAME
	SALARY

```
@Embeddable
public class EmployeeId
    private String country;
    @Column(name="EMP_ID")
    private int id;

    public EmployeeId() {}
    public EmployeeId(String country,
        int id) {
        this.country = country;
        this.id = id;
    }
    // ...
}
```

```
@Entity
public class Employee {
    @EmbeddedId private EmployeeId id;
    private String name;
    private long salary;
    // ...
    public String getCountry() {return id.getCountry();}
    public int getId() {return id.getId();}
    // ...
}
```

Compound primary keys

Embedded Id Class

EMPLOYEE	
PK	<u>COUNTRY</u>
PK	<u>EMP_ID</u>
	NAME
	SALARY

```
@Embeddable
public class EmployeeId
    private String country;
    @Column(name="EMP_ID")
    private int id;

    public EmployeeId() {}
    public EmployeeId(String country,
        int id) {
        this.country = country;
        this.id = id;
    }
}
```

Referencing an embedded IdClass in a query:

```
em.createQuery("SELECT e FROM Employee e " +
    "WHERE e.id.country = ?1 AND e.id.id = @2")
    .setParameter(1, country)
    .setParameter(2, id)
    .getSingleResult();
```

Shared Primary Key

Bidirectional one-to-one relationship between Employee and EmployeeHistory

```
@Entity
public class EmployeeHistory
    // ...
    @Id
    @OneToOne
    @JoinColumn(name="EMP_ID")
    private Employee employee;
    // ...
}
```

The primary key type of EmployeeHistory is the same as primary key of Employee.

- If <pk> of Employee is integer, <pk> of EmployeeHistory will be also integer.
- If Employee has a compound <pk>, either with an id class or an embedded id class, then EmployeeHistory will share the same id class and should also be annotated
- @IdClass.

The rule is that a primary key attribute corresponds to a relationship attribute. However, the relationship attribute is missing in this case (the id class is shared between both parent and dependent entities). Hence, this is an exception from the above mentioned rule.

Shared Primary Key

Bidirectional one-to-one relationship between Employee and EmployeeHistory

```
@Entity
public class EmployeeHistory
    // ...
    @Id
    int empld;

    @MapsId
    @OneToOne
    @JoinColumn(name="EMP_ID")
    private Employee employee;
    // ...
}
```

On the previous slide, the relationship attribute was missing.

In this case, the EmployeeHistory class contains both a primary key attribute as well as the relationship attribute. Both attributes are mapped to the same foreign key column in the table.

@MapsId annotates the relationship attribute to indicate that it is mapping the id attribute as well (**read-only mapping!**). Updates/inserts to the foreign key column will only occur through the relationship attribute.

=> YOU MUST ALWAYS SET THE PARENT RELATIONSHIPS BEFORE TRYING TO PERSIST A DEPENDENT ENTITY.

Read-only mappings

The constraints are checked on commit!
Hence, the constrained properties can be Modified in memory.

```
@Entity
public class Employee
    @Id
    @Column(insertable=false)
    private int id;

    @Column(insertable=false, updatable=false)
    private String name;

    @Column(insertable=false, updatable=false)
    private long salary;

    @ManyToOne
    @JoinColumn(name="DEPT_ID", insertable=false, updatable=false)
    private Department department;
    // ...
```

Optionality

```
@Entity
public class Employee
    // ...

    @ManyToOne(optional=false)
    @JoinColumn(name="DEPT_ID", insertable=false, updatable=false)
    private Department department;
    // ...
}
```

Compound Join Columns

EMPLOYEE	
PK	<u>COUNTRY</u>
PK	<u>EMP_ID</u>
	NAME
	SALARY
FK1	MGR_COUNTRY
FK1	MGR_ID

@Entity

@IdClass(EmployeeId.class)

```
public class Employee {
```

```
    @Id private String country;
```

```
    @Id
```

```
    @Column name="EMP_ID")
```

```
    private int id;
```

```
    @ManyToOne
```

```
    @JoinColumns({
```

```
        @JoinColumn(name="MGR_COUNTRY",  
                    referencedColumnName="COUNTRY"),
```

```
        @JoinColumn(name="MGR_ID",  
                    referencedColumnName="EMP_ID")
```

```
    })
```

```
    private Employee manager;
```

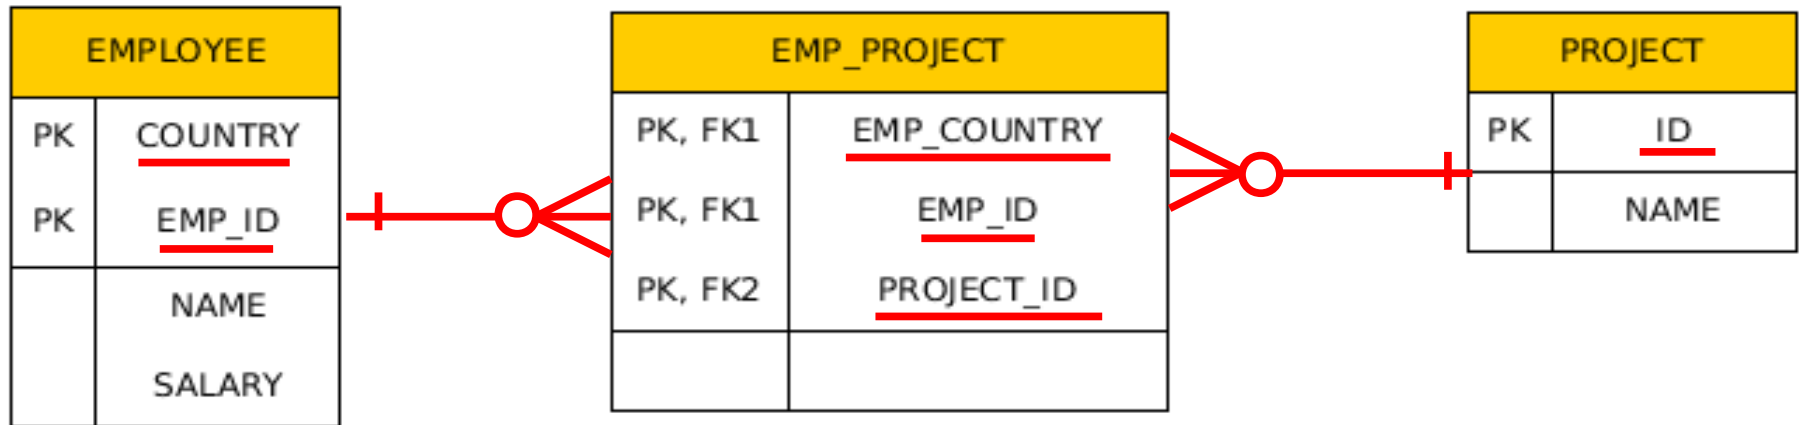

```
    @OneToMany(mappedBy="manager")
```

```
    private Collection<Employee> directs;
```

```
    // ...
```

```
}
```

Compound Join Columns

@Entity

@IdClass(EmployeeId.class)

```
public class Employee
```

```
    @Id private String country;
```

```
    @Id
```

```
    @Column(name="EMP_ID")
```

```
    private int id;
```

```
    @ManyToMany
```

```
    @JoinTable(
```

```
        name="EMP_PROJECT",
```

```
        joinColumns={
```

```
            @JoinColumn(name="EMP_COUNTRY", referencedColumnName="COUNTRY"),
```

```
            @JoinColumn(name="EMP_ID", referencedColumnName="EMP_ID")},
```

```
        inverseJoinColumns=@JoinColumn(name="PROJECT_ID"))
```

```
    private Collection<Project> projects;
```

Inheritance

- How to map inheritance into RDBMS ?

Strategies for inheritance mapping

- Single table

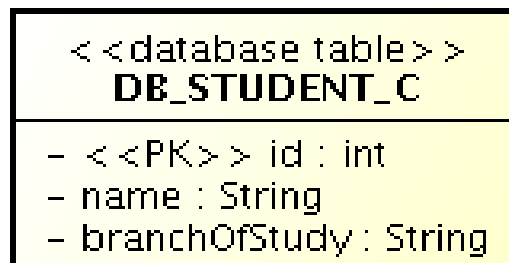

- Joined

Strategies for inheritance mapping

- Table-per-concrete-class

Inheritance mapping

single-table strategy

```
@Entity
@Table(name="DB_PERSON_C")
@Inheritance //same as @Inheritance(strategy=InheritanceType.SINGLE_TABLE)
@DiscriminationColumn(name="EMP_TYPE")
public abstract class Person { ...}
```

```
@Entity
@DiscriminatorValue("Emp")
Public class Employee extends Person {...}
```

```
@Entity
@DiscriminatorValue("Stud")
Public class Student extends Person {...}
```

Inheritance mapping

joined strategy

```
@Entity
@Table(name="DB_PERSON_C")
@Inheritance(strategy=InheritanceType.JOINED)
@DiscriminationColumn(name="EMP_TYPE",
    discriminatorType=discriminatorType.INTEGER)
public abstract class Person { ...}
```

```
@Entity
@Table(name="DB_EMPLOYEE_C")
@DiscriminatorValue("1")
public class Employee extends Person { ...}
```

```
@Entity
@Table(name="DB_STUDENT_C")
@DiscriminatorValue("2")
public class Student extends Person { ...}
```

Inheritance mapping

table-per-concrete-class strategy

```
@Entity
```

```
@Table(name="DB_PERSON_C")
```

```
public abstract class Person { ... }
```

```
@Entity
```

```
@Table(name="DB_EMPLOYEE_C")
```

```
@AttributeOverride(name="name", column=@Column(name="FULLNAME"))
```

```
@DiscriminatorValue("1")
```

```
public class Employee extends Person {...}
```

```
@Entity
```

```
@Table(name="DB_STUDENT_C")
```

```
@DiscriminatorValue("2")
```

```
public class Student extends Person {...}
```

Strategies for inheritance mapping

- If Person is not an @Entity, but a @MappedSuperClass

- If Person is not an @Entity, neither @MappedSuperClass, the deploy fails as the @Id is in the Person (non-entity) class.

Queries

- JPQL (Java Persistence Query Language)
- Native queries (SQL)

JPQL

JPQL very similar to SQL (especially in JPA 2.0)

```
SELECT p.number  
FROM Employee e JOIN e.phones p  
WHERE e.department.name = 'NA42' AND p.type = 'CELL'
```

Conditions do not stick on values of database columns, but on entities and their properties.

```
SELECT d, COUNT(e), MAX(e.salary), AVG(e.salary)  
FROM Department d JOIN d.employees e  
GROUP BY d  
HAVING COUNT(e) >= 5
```

JPQL – query parameters

- positional

```
SELECT e  
FROM Employee e  
WHERE e.department = ?1 AND e.salary > ?2
```

- named

```
SELECT e  
FROM Employee e  
WHERE e.department = :dept AND salary > :base
```

JPQL – defining a query dynamically

```
@Stateless
public class QueryServiceBean implements QueryService {
    @PersistenceContext(unitName="DynamicQueries")
    EntityManager em;

    public long queryEmpSalary(String deptName, String empName)
    {
        String query = "SELECT e.salary FROM Employee e " +
            "WHERE e.department.name = '" + deptName +
            "' AND e.name = '" + empName + "'";
        return em.createQuery(query, Long.class)
            .getSingleResult();
    }
}
```

JPQL – using parameters

```
String QUERY = "SELECT e.salary FROM Employee e " +  
    "WHERE e.department.name = :deptName " +  
    "AND e.name = :empName";  
  
public long queryEmpSalary(String deptName, String empName) {  
    return em.createQuery(QUERY, Long.class)  
        .setParameter("deptName", deptName)  
        .setParameter("empName", empName)  
        .getSingleResult();  
}
```

JPQL – named queries

```
@NamedQuery(name="Employee.findByName",  
            query="SELECT e FROM Employee e "  
                +  
                "WHERE e.name = :name")
```

```
public Employee findEmployeeByName(String name) {  
    return em.createNamedQuery("Employee.findByName",  
                               Employee.class)  
                .setParameter("name", name)  
                .getSingleResult();  
}
```

JPQL – named queries

```
@NamedQuery(name="Employee.findByDept",  
            query="SELECT e FROM Employee e " +  
                "WHERE e.department = ?1")
```

```
public void printEmployeesForDepartment(String dept) {  
    List<Employee> result =  
        em.createNamedQuery("Employee.findByDept",  
                            Employee.class)  
            .setParameter(1, dept)  
            .getResultList();  
    int count = 0;  
    for (Employee e: result) {  
        System.out.println(++count + ":" + e.getName);  
    }  
}
```

JPQL – pagination

```
private long pageSize = 800;
private long currentPage = 0;

public List getCurrentResults() {
    return em.createNamedQuery("Employee.findByDept",
        Employee.class)
        .setFirstResult(currentPage * pageSize)
        .setMaxResults(pageSize)
        .getResultList();
}

public void next() {
    currentPage++;
}
```

JPQL – bulk updates

Modifications of entities not only by `em.persist()` or `em.remove()`;

```
em.createQuery("UPDATE Employee e SET e.manager = ?1 " +  
              "WHERE e.department = ?2")  
  .setParameter(1, manager)  
  .setParameter(2, dept)  
  .executeUpdate();
```

```
em.createQuery("DELETE FROM Project p ,, +  
              "WHERE p.employees IS EMPTY")  
  .executeUpdate();
```

If REMOVE cascade option is set for a relationship, cascading remove occurs.

Native SQL update and delete operations should not be applied to tables mapped by an entity (transaction, cascading).

Native (SQL) queries

```
@NamedNativeQuery(  
    name="getStructureReportingTo",  
    query = "SELECT emp_id, name, salary, manager_id," +  
            "dept_id, address_id " +  
            "FROM emp ",  
    resultClass = Employee.class  
)
```

Mapping is straightforward

Native (SQL) queries

```
@NamedNativeQuery(  
    name="getEmployeeAddress",  
    query = "SELECT emp_id, name, salary, manager_id," +  
            "dept_id, address_id, id, street, city, " +  
            "state, zip " +  
            "FROM emp JOIN address "  
            "ON emp.address_id = address.id)"  
)
```

Mapping less straightforward

```
@SqlResultSetMapping(  
    name="EmployeeWithAddress",  
    entities={@EntityResult(entityClass=Employee.class),  
              @EntityResult(entityClass=Address.class)}
```

Native (SQL) queries

```
Query q = em.createNativeQuery(
    "SELECT o.id AS order_id, " +
        "o.quantity AS order_quantity, " +
        "o.item AS order_item, " +
        "i.name AS item_name, " +
    "FROM Order o, Item i " +
    "WHERE (order_quantity > 25) AND (order_item = i.id)",
    "OrderResults");

@SqlResultSetMapping(name="OrderResults",
    entities={
        @EntityResult(entityClass=com.acme.Order.class,
            fields={
                @FieldResult(name="id", column="order_id"),
                @FieldResult(name="quantity",
                    column="order_quantity"),
                @FieldResult(name="item",
                    column="order_item")
            })
    },
    columns={
        @ColumnResult(name="item_name")
    }
)
```
