Minimax

- **function** minimax(node, depth, Player)
- **if** (depth = 0 or node is a terminal node) **return** evaluation value of node
- **if** (Player = MaxPlayer)
- **for each** child of node
- $v := \max(v, \text{minimax}(\text{child}, \text{depth}-1, \text{switch}(\text{Player}))$)
-
- **return** v
- **else**
- **for each** child of node
- $v := \min(v, \text{minimax}(\text{child}, \text{depth}-1, \text{switch}(\text{Player}))$)
-
- **return** v

Alpha-Beta Pruning

- **function** alphabeta(node, depth, α , β , Player)
- **if** (depth = 0 or node is a terminal node) **return** evaluation value of node
- **if** (Player = MaxPlayer)
- **for each** child of node
- $v := \max(v, \text{alphabeta}(\text{child}, \text{depth}-1, \alpha, \beta, \text{switch}(\text{Player})))$
- $\alpha := \max(\alpha, v)$; **if** ($\beta \leq \alpha$) **break**
- **return** v
- **else**
- **for each** child of node
- $v := \min(v, \text{alphabeta}(\text{child}, \text{depth}-1, \alpha, \beta, \text{switch}(\text{Player})))$
- $\beta := \min(\beta, v)$; **if** ($\beta \leq \alpha$) **break**
- **return** v

Game

Negamax

- **function** negamax(node, depth, α , β , Player)
- **if** (depth = 0 or node is a terminal node) **return** evaluation value of node
- **if** (Player = MaxPlayer)
- **for each** child of node
- $v := \max(v, -\text{negamax}(\text{child}, \text{depth}-1, -\beta, -\alpha, \text{switch}(\text{Player}))$)
- $\alpha := \max(\alpha, v)$; **if** ($\beta \leq \alpha$) **break**
- **return** v
- **else**
- **for each** child of node
- $v := \min(v, \text{alphabeta}(\text{child}, \text{depth}-1, \alpha, \beta, \text{switch}(\text{Player}))$)
- $\beta := \min(\beta, v)$; **if** ($\beta \leq \alpha$) **break**
- **return** v

NegaScout – Main Idea

- enhancement of the alpha-beta algorithm
- assumes some heuristic that determines move ordering
 - the algorithm assumes that the first action is the best one
 - after evaluating the first action, the algorithm checks whether the remaining actions are worse
- the “test” is performed via null-window search
 - $[\alpha, \alpha+1]$
 - the algorithm needs to re-search, if the test fails (i.e., there might be a better outcome for the player when following the tested action)

.

NegaScout

function negascout(node, depth, α , β , Player)

- **if** ((depth = 0) or (node is a terminal node)) **return** eval(node)
- $b := \beta$
- **for each** child of node
 - $v := \max(v, -\text{negascout}(\text{child}, \text{depth}-1, -b, -\alpha, \text{switch}(\text{Player})))$
 - **if** (($\alpha < v$) and (child is not the first child))
 - $v := \max(v, -\text{negascout}(\text{child}, \text{depth}-1, -\beta, -\alpha, \text{switch}(\text{Player})))$
 - $\alpha := \max(\alpha, v)$
 - **if** ($\beta \leq \alpha$) **break**
 - $b := \alpha + 1$
- **return** v

NegaScout

function negascout(node, depth, α , β , Player)

- **if** ((depth = 0) or (node is a terminal node)) **return** eval(node)
- $b := \beta$
- **for each** child of node
- $v := \max(v, -\text{negascout}(\text{child}, \text{depth}-1, -b, -\alpha, \text{switch}(\text{Player})))$
- **if** (($\alpha < v < \beta$) and (child is not the first child))
- $v := \max(v, -\text{negascout}(\text{child}, \text{depth}-1, -\beta, -v, \text{switch}(\text{Player})))$
- $\alpha := \max(\alpha, v)$
- **if** ($\beta \leq \alpha$) **break**
- $b := \alpha + 1$
- **return** v

Alpha Beta and Negascout in Practice

- Extracting selected moves
- Cache for previous results (transposition tables)
- Iterative deepening (using previous results in game playing)
- Implementation of game states (bit operations, modifications have to be as quick as possible)

Alpha Beta and Negascout in Practice

- TEST on alpha beta and negascout
 - **3.4. and 4.4. 2017 on seminars**
