		Overview of the Lecture	
Introduction to Object Oriented Programming in C++ Jan Faigl Department of Computer Science Faculty of Electrical Engineering Czech Technical University in Prague Lecture 10		<ul> <li>Part 1 – Brief Overview of C89 vs C99 vs C11         <ul> <li>C89 vs C99</li> <li>C11</li> <li>K. N. King: Appendix B</li> </ul> </li> <li>Part 2 – Object Oriented Programming (in C++)         <ul> <li>Differences between C and C++</li> <li>Classes and Objects</li> <li>Constructor/Destructor</li> <li>Example – Class Matrix</li> </ul> </li> </ul>	
Jan Faigl, 2016 C89 vs C99 Part I Part 1 – Brief Overview of C89 vs C99 C11	<u>1 / 48</u> C11		
Jan Faigl, 2016 B3B36PRG – Lecture 10: OOP in C++ (Part 1)	3 / 48	<ul> <li>be rounded either up or down. The sign of i % j for negative i o depends on the implementation.</li> <li>In C99, the result is always truncated toward zero and the sign of i % j is the sign of i.</li> <li>B3B36PRG - Lecture 10: OOP in C++ (Part 1)</li> </ul>	or j

C89	vs	C99
C09	v 3	C99

## Differences between C89 and C99

- Bool type C99 provides \_Bool type and macros in stdbool.h
- Loops C99 allows to declare control variable(s) in the first statement of the for loop
- Arrays C99 has
  - designated initializers and also allows
  - to use variable-length arrays
- *Functions* one of the directly visible changes is
  - In C89, declarations must precede statements within a block. In C99, it cam be mixed.
- Preprocessor e.g.,
  - C99 allows macros with a variable number of arguments
  - C99 introduces <u>\_\_func\_\_</u> macro which behaves as a string variable that stores the name of the currently executing function
- Input/Output conversion specification for the \*printf() and \*scanf() functions has been significantly changed in C99.

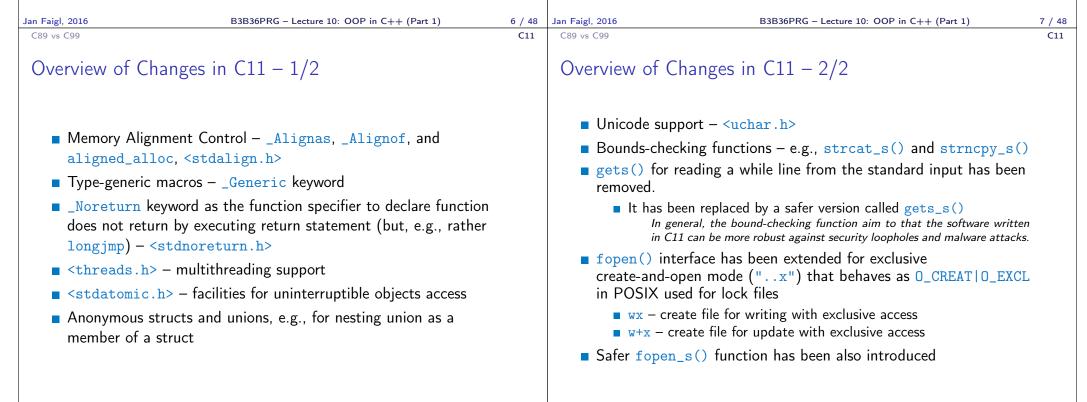

## C89 vs C99

C11

## Differences between C89 and C99 – Additional Libraries

- <stdbool.h> macros false and true that denote the logical values 0 and 1, respectively
- stdint.h> integer types with specified widths
- <inttypes.h> macros for input/output of types specified in
  <stdint.h>
- <complex.h> functions to perform mathematical operations on complex numbers
- <tgmath.h> type-generic macros for easier call of functions
  defined in <math.h> and <complex.h>
- <fenv.h> provides access to floating-point status flags and control modes

Further changes, e.g., see K. N. King: Appendix B

```
Differences between C and C++
                           Classes and Objects
                                            Constructor/Destructor
                                                                Example - Class Matrix
                                                                                    Differences between C and C++
                                                                                                              Classes and Objects
                                                                                                                                Constructor/Destructor
                                                                                                                                                    Example - Class Matrix
                                                                                    Example – Constructor Calling 1/3
 Constructor Overloading
    • An example of constructor for creating an instance of the complex
                                                                                        We can create a dedicated initialization method that is called from
       number
                                                                                          different constructors
    In an object initialization, we may specify only real part or both
                                                                                         class Complex {
      the real and imaginary part
                                                                                             public:
            class Complex {
                                                                                                Complex(double r, double i) { init(r, i); }
               public:
                                                                                                Complex(double r) { init(r, 0.0); }
                   Complex(double r)
                                                                                                Complex() { init(0.0, 0.0); }
                       re = r;
                                                                                             private:
                   Complex(double r, double i)
                                                                                                void init(double r, double i)
                                                                                                ł
                       re = r;
                                                                                                    re = r;
                       im = i;
                                                                                                    im = i:
                                                                                                }
                   ~Complex() { /* nothing to do in destructor */ }
                                                                                             private:
               private:
                                                                                                double re;
                   double re;
                                                                                                double im;
                   double im;
                                                                                         };
            }:
                  Both constructors shared the duplicate code, which we like to avoid!
                                                                            26 / 48
                                B3B36PRG - Lecture 10: OOP in C++ (Part 1)
                                                                                   Jan Faigl, 2016
                                                                                                                    B3B36PRG - Lecture 10: OOP in C++ (Part 1)
                                                                                                                                                               27 / 48

 Differences between C and C++
                           Classes and Objects
                                            Constructor/Destructor
                                                                Example - Class Matrix
                                                                                    Differences between C and C++
                                                                                                              Classes and Objects
                                                                                                                               Constructor/Destructor
                                                                                                                                                    Example - Class Matrix
 Example – Constructor Calling 2/3
                                                                                    Example – Constructor Calling 3/3
    • Or we can utilize default values of the arguments that is combined
                                                                                        ■ Alternatively, in C++11, we can use delegating constructor
      with initializer list here
                                                                                       class Complex {
   class Complex {
                                                                                           public:
       public:
                                                                                              Complex(double r, double i)
           Complex(double r = 0.0, double i = 0.0) : re(r), im(i) {}
                                                                                              {
       private:
                                                                                                  re = r;
           double re;
                                                                                                  im = i;
           double im;
   };
                                                                                              Complex(double r) : Complex(r, 0.0) {}
   int main(void)
                                                                                              Complex() : Complex(0.0, 0.0) \{\}
   {
                                                                                           private:
       Complex c1;

                                                                                       Differences between C and C++
                                                                                                                   Classes and Objects
                                                                                                                                     Constructor/Destructor
                                                                                                                                                          Example - Class Matrix
 Example - Class Matrix - Exception Handling
                                                                                       Example – Class Matrix – Printing the Matrix
    The code where an exception can be raised is put into the
                                                                                           • We create a print() method to nicely print the matrix to the
      try-catch block
                                                                                             standard output
    The particular exception is specified in the catch by the class name
                                                                                           Formatting is controlled by i/o stream manipulators defined in
    • We use the program standard output denoted as std::cout
                                                                                              <iomanip> header file
                                     We can avoid std:: by using namespace std;
                                                                                          #include <iostream>
   #include <iostream>
                                                       Or just using std::cout;
                                                                                          #include <iomanip>
   #include "matrix.h"
                                                                                          #include "matrix.h"
   int main(void)
                                                                                          void print(const Matrix& m)
   ſ
       int ret = 0:
       trv {
                                                                                              std::cout << std::fixed << std::setprecision(1);</pre>
          Matrix m1(3, 3);

B3B36PRG - Lecture 10: OOP in C++ (Part 1) 37 / 48 Jan Faigl, 2016 B3B36PRG - Lecture 10: OOP in C++ (Part 1)

```
Differences between C and C++
                           Classes and Objects
                                             Constructor/Destructor
                                                                  Example - Class Matrix
                                                                                      Differences between C and C++
                                                                                                                 Classes and Objects
                                                                                                                                   Constructor/Destructor
                                                                                                                                                       Example - Class Matrix
                                                                                      Example - Class Matrix - Copy Constructor
 Example – Class Matrix – Printing the Matrix
    ■ Notice, the matrix variable m1 is not copied when it is passed to
                                                                                          We may overload the constructor to create an copy of the object
      print() function because of passing reference
       #include <iostream>
                                                                                          class Matrix {
                                                                                             public:
      #include <iomanip>
      #include "matrix.h"
                                                                                                Matrix(const Matrix &m);
      void print(const Matrix& m);
                                                                                          };
      int main(void)
                                                                                          We create an exact copy of the matrix
          int ret = 0;
                                                                                          Matrix::Matrix(const Matrix &m) : ROWS(m.ROWS), COLS(m.COLS)
          trv {
                                                                                          { // copy constructor
             Matrix m1(3, 3);
                                                                                             vals = new double[ROWS * COLS];
             m1.fillRandom();
             std::cout << "Matrix m1" << std::endl;</pre>
                                                                                             for (int i = 0; i < ROWS * COLS; ++i) {</pre>
             print(m1);
                                                                                                 vals[i] = m.vals[i];
    Example of the output
                                                                                          Notice, access to private fields is allowed within in the class
       clang++ --pedantic matrix.cc demo-matrix.cc && ./a.out
      Matrix m1
                                                                                                        We are implementing the class, and thus we are aware what are the

                                                                  Example - Class Matrix
                                                                                      Differences between C and C++
                                                                                                                                   Constructor/Destructor
                                                                                                                                                       Example - Class Matrix
 Example – Class Matrix – Dynamic Object Allocation
                                                                                      Example – Class Matrix – Sum
                                                                                          The method to sum two matrices will return a new matrix
    • We can create a new instance of the object by the new operator
                                                                                          class Matrix {
                                                                                             public:
    We may also combine dynamic allocation with the copy constructor
                                                                                                Matrix sum(const Matrix &m2);
    Notice, the access to the methods of the object using the pointer
                                                                                         The variable ret is passed using the copy constructor
      to the object is by the -> operator
                                                                                          Matrix Matrix::sum(const Matrix &m2)
                                                                                          ſ
     ratrix m1(3, 3);
                                                                                             if (ROWS != m2.ROWS or COLS != m2.COLS) {
     m1.fillRandom();
                                                                                                throw std::invalid_argument("Matrix dimensions do not match at
     std::cout << "Matrix m1" << std::endl;</pre>
                                                                                              Matrix::sum");
     print(m1);
                                                                                             }
                                                                                             Matrix ret(ROWS, COLS);
     Matrix *m2 = new Matrix(m1);
                                                                                             for (int i = 0; i < ROWS * COLS; ++i) {</pre>
     Matrix *m3 = new Matrix(m2->rows(), m2->cols());
                                                                                                ret.vals[i] = vals[i] + m2.vals[i];
     std::cout << std::endl << "Matrix m2" << std::endl;</pre>
                                                                                             }
     print(*m2);
     m3->fillRandom();
                                                                                             return ret;
                                                                                                             We may also implement sum as addition to the particular matrix
     std::cout << std::endl << "Matrix m3" << std::endl;</pre>
                                                                                          The sum() method can be than used as any other method
     print(*m3);
                                                                                          Matrix m1(3, 3);
     delete m2;
                                                                                          m1.fillRandom();
     delete m3;
                                                                                          Matrix *m2 = new Matrix(m1);
                                                       lec10/demo-matrix.cc
                                                                                          Matrix m4 = m1.sum(*m2);

 Example - Class Matrix - Operator +
                                                                                          Example – Class Matrix – Output Stream Operator
    In C++, we can define our own operators, e.g., + for sum of two
                                                                                             A output stream operator << can be defined to pass Matrix
       matrices
                                                                                                objects directly to the output stream
                                                                                              #include <ostream>
    It will be called like the sum() method
                                                                                              class Matrix { ... };
       class Matrix {
                                                                                              std::ostream& operator<<(std::ostream& out, const Matrix& m);</pre>
          public:
                                                                                             It is defined outside the Matrix
             Matrix sum(const Matrix &m2);
             Matrix operator+(const Matrix &m2);
                                                                                              #include <iomanip>
       }
                                                                                              std::ostream& operator<<(std::ostream& out, const Matrix& m)
                                                                                              ſ
    ■ In our case, we can use the already implemented sum() method
                                                                                                 if (out) {
       Matrix Matrix::operator+(const Matrix &m2)
                                                                                                    out << std::fixed << std::setprecision(1);</pre>
       {
                                                                                                    for (int r = 0; r < m.rows(); ++r) {</pre>
          return sum(m2);
                                                                                                       for (int c = 0; c < m.cols(); ++c) {</pre>
       }
                                                                                                          out << (c > 0 ? " " : "") << std::setw(4);</pre>
                                                                                                          out << m.getValueAt(r, c);</pre>
    The new operator can be applied for the operands of the Matrix
                                                                                                       }
       type like as to default types
                                                                                                       out << std::endl;</pre>
                                                                                                    }
       Matrix m1(3,3);
                                                                                                }
                                                                                                                  "Outside" operator can be used in an output stream pipeline with other
       m1.fillRandom();
                                                                                                 return out;
                                                                                                                  data types. In this case, we can use just the public methods. But, if
       Matrix m2(m1), m3(m1 + m2); // use sum of m1 and m2 to init m3
                                                                                                                  needed, we can declare the operator as a friend method to the class,
                                                                                              }
       print(m3);
                                                                                                                  which can access the private fields.
