Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition	Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition
Inheritance	Example MatrixExt – Extension of the Matrix
 Founding definition and implementation of one class on another existing class(es) Let class <i>B</i> be inherited from the class <i>A</i>, then Class <i>B</i> is subclass or the derived class of <i>A</i> Class <i>A</i> is superclass or the base class of <i>B</i> The subclass <i>B</i> has two parts in general: Derived part is inherited from <i>A</i> New incremental part contains definitions and implementation added by the class <i>B</i> The inheritance is relationship of the type is-a Object of the type <i>B</i> is also an instance of the object of the type <i>A</i> Properties of <i>B</i> inherited from the <i>A</i> can be redefined Change of field visibility (protected, public, private) Overriding of the method implementation Using inheritance we can create hierarchies of objects Implement general function in superclasses or creating abstract classes that are further specialized in the derived classes. 	 We will extend the existing class Matrix to have identity method and also multiplication operator We refer the superclass as the Base class using typedef We need to provide a constructor for the MatrixExt; however, we used the existing constructor in the base class class MatrixExt : public Matrix { typedef Matrix Base; // typedef for refering the superclass public: MatrixExt(int r, int c) : Base(r, c) {} // base constructor void setIdentity(void); Matrix operator*(const Matrix &m2); };
Jan Faigl, 2017 B3B36PRG – Lecture 11: OOP in C++ (Part 2) 12 / 48 Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition	Jan Faigl, 2017 B3B36PRG – Lecture 11: OOP in C++ (Part 2) 13 / 48 Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition
Example MatrixExt – Identity and Multiplication Operator We can use only the public (or protected) methods of Matrix class #include "matrix_ext.h" Matrix does not have any protected members	 Example MatrixExt – Example of Usage 1/2 Objects of the class MatrixExt also have the methods of the Matrix
<pre>void MatrixExt::setIdentity(void)</pre>	Matrix
<pre>{ for (int r = 0; r < rows(); ++r) {</pre>	#include <iostream> clang++ matrix.cc matrix_ext. #include "matrix_ext.h" cc demo-matrix_ext.cc &&</iostream>
for (int $c = 0$; $c < cols()$; ++c) {	
(*this)(r, c) = (r == c) ? 1.0 : 0.0;	./a.out using std::cout; Matrix m1:
(*this)(r, c) = (r == c) ? 1.0 : 0.0; } }	
<pre>} } Matrix MatrixExt::operator*(const Matrix &m2) { Matrix m3(rows(), m2.cols());</pre>	<pre>using std::cout; Matrix m1:</pre>
<pre>} } August State St</pre>	<pre>using std::cout; Matrix m1:</pre>
<pre>} } Matrix MatrixExt::operator*(const Matrix &m2) { Matrix m3(rows(), m2.cols()); for (int r = 0; r < rows(); ++r) { for (int c = 0; c < m2.cols(); ++c) { m3(r, c) = 0.0; } }</pre>	<pre>using std::cout; Matrix m1:</pre>
<pre>} } Atrix MatrixExt::operator*(const Matrix &m2) { Matrix m3(rows(), m2.cols()); for (int r = 0; r < rows(); ++r) { for (int c = 0; c < m2.cols(); ++c) { m3(r, c) = 0.0; for (int k = 0; k < cols(); ++k) { m3(r, c) += (*this)(r, k) * m2(k, c); } } return m3;</pre>	<pre>using std::cout; Matrix m1:</pre>
<pre> } } } Matrix MatrixExt::operator*(const Matrix &m2) { Matrix m3(rows(), m2.cols()); for (int r = 0; r < rows(); ++r) { for (int c = 0; c < m2.cols(); ++c) { m3(r, c) = 0.0; for (int k = 0; k < cols(); ++k) { m3(r, c) += (*this)(r, k) * m2(k, c); } } return m3; } lec11/matrix_ext.cc </pre>	<pre>using std::cout; Matrix m1:</pre>

Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition	Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition
Example MatrixExt – Example of Usage 2/2	Categories of the Inheritance
 We may use objects of MatrixExt anywhere objects of Matrix can be applied. This is a result of the inheritance <pre>And a first step towards polymorphism</pre>	 Strict inheritance – derived class takes all of the superclass and adds own methods and attributes. All members of the superclass are available in the derived class. It strictly follows the is-a hierarchy Nonstrict inheritance – the subclass derives from the a superclass only certain attributes or methods that can be further redefined Multiple inheritance – a class is derived from several superclasses
an Faigl, 2017 B3B36PRG - Lecture 11: OOP in C++ (Part 2) 16 / 48 Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition Inheritance - Summary	Jan Faigl, 2017 B3B36PRG – Lecture 11: OOP in C++ (Part 2) 17 / 44 Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition Polymorphism
 Inheritance is a mechanism that allows Extend data field of the class and modify them Extend or modify methods of the class Inheritance allows to Create hierarchies of classes "Pass" data fields and methods for further extension and modification Specialize (specify) classes The main advantages of inheritance are It contributes essentially to the code reusability Inheritance is foundation for the polymorphism 	 Polymorphism can be expressed as the ability to refer in a same way to different objects We can call the same method names on different objects We work with an object whose actual content is determined at the runtime Polymorphism of objects - Let the class B be a subclass of A, then the object of the B can be used wherever it is expected to be an object of the class A Polymorphism of methods requires dynamic binding, i.e., static vs. dynamic type of the class Let the class B be a subclass of A and redefines the method m() A variable x is of the static type B, but its dynamic type can be A or B Which method is actually called for x.m() depends on the dynamic type
an Faigl, 2017 B3B36PRG - Lecture 11: OOP in C++ (Part 2) 18 / 48	Jan Faigl, 2017 B3B36PRG – Lecture 11: OOP in C++ (Part 2) 20 / 48

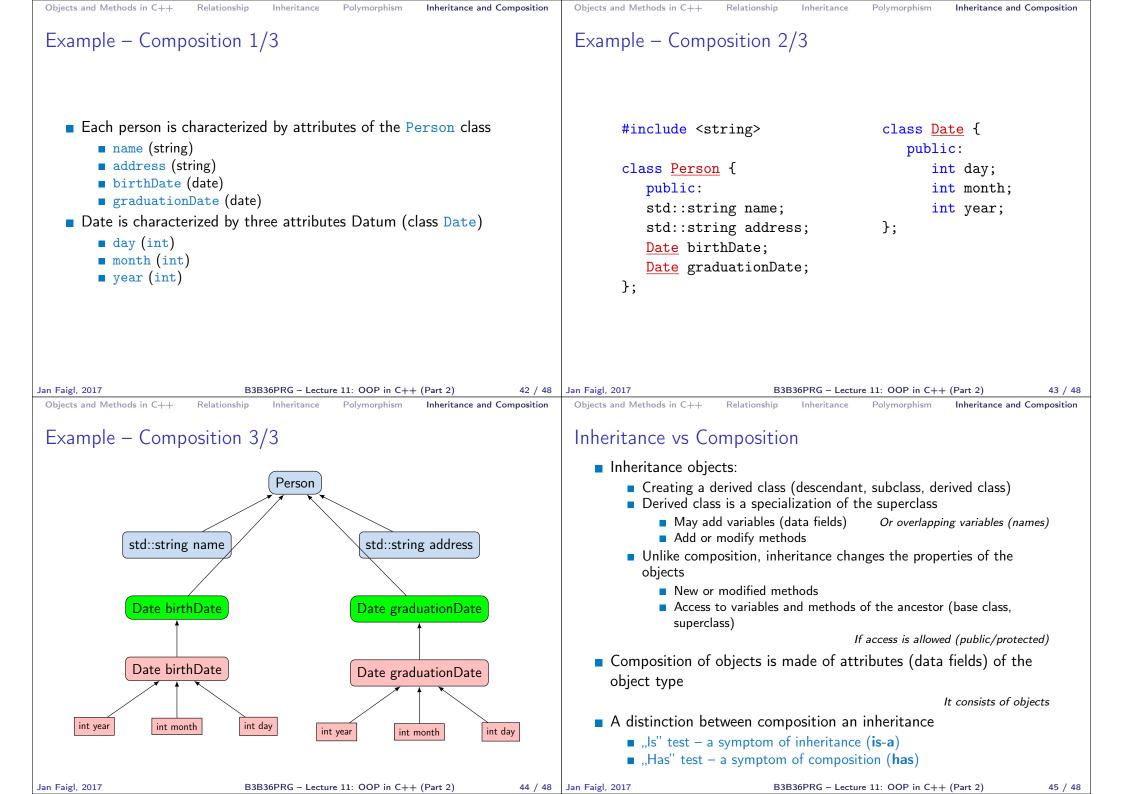

```
Objects and Methods in C++
                         Relationship
                                     Inheritance
                                                Polymorphism
                                                             Inheritance and Composition
                                                                                     Objects and Methods in C++
                                                                                                             Relationship
                                                                                                                          Inheritance
                                                                                                                                     Polymorphism
                                                                                                                                                  Inheritance and Composition
 Example – Overriding with Virtual Method 2/2
                                                                                     Derived Classes, Polymorphism, and Practical Implications
   #include <iostream>
                                                   clang++ demo-virtual.cc
   using namespace std:
                                                   ./a.out
   class A {
                                                   Object of the class A
                                                                                         Derived class inherits the methods and data fields of the
      public:
                                                   Object of the class B
                                                                                           superclass, but it can also add new methods and data fields
         virtual void info() // Virtual !!!
                                                   Object of the class B
                                                                                              It can extend and specialize the class
         ſ
            cout << "Object of the class A" << endl;</pre>
                                                                                              It can modify the implementation of the methods
         }
                                                                                        An object of the derived class can be used instead of the object of
   };
                                                                                           the superclass, e.g.,
   class B : public A {
      public:
                                                                                              We can implement more efficient matrix multiplication without
         void info()
                                                                                                modification of the whole program
         ſ
                                                                                                       We may further need a mechanism to create new object based on the
            cout << "Object of the class B" << endl;</pre>
         }
                                                                                                       dynamic type, i.e., using the newInstance virtual method
   };
                                                                                         Virtual methods are important for the polymorphism
                                                                                              It is crucial to use a virtual destructor for a proper destruction of
   A* a = new A(); B* b = new B();
   a->info(); // calling method info() of the class A
                                                                                                the object
   b->info(); // calling method info() of the class B
                                                                                                                   E.g., when a derived class allocate additional memory
   a = b; // use the polymorphism of objects
   a->info(); // the dynamic binding exists, method of the class B is called
   delete a; delete b;
                                                     lec11/demo-virtual.cc

                                 B3B36PRG - Lecture 11: OOP in C++ (Part 2)
                                                                            25 / 48
                                                                                    Jan Faigl, 2017
                                                                                                                     B3B36PRG - Lecture 11: OOP in C++ (Part 2)
                                                                                                                                                                 26 / 48
 Objects and Methods in C++
                         Relationship
                                     Inheritance
                                                Polymorphism
                                                             Inheritance and Composition
                                                                                     Objects and Methods in C++
                                                                                                              Relationship
                                                                                                                          Inheritance
                                                                                                                                     Polymorphism
                                                                                                                                                  Inheritance and Composition
 Example – Virtual Destructor 1/4
                                                                                     Example – Virtual Destructor 2/4
   #include <iostream>
                                                                                     class Derived : public Base {
   using namespace std;
                                                                                         public:
   class Base {
                                                                                             Derived(int capacity) : Base(capacity) {
       public:
                                                                                                 cout << "Derived::Derived -- allocate data2" << endl:</pre>
           Base(int capacity) {
                                                                                                 int *data2 = new int[capacity];
               cout << "Base::Base -- allocate data" << endl;</pre>
                                                                                             }
               int *data = new int[capacity];
                                                                                             ~Derived() {
           }
                                                                                                 cout << "Derived:: Derived -- release data2" << endl:</pre>
           virtual ~Base() { // virtual destructor is important
                                                                                                 int *data2;
               cout << "Base::~Base -- release data" << endl;</pre>
                                                                                             }
           }
                                                                                         protected:
       protected:
                                                                                             int *data2:
           int *data;
                                                                                     };
   };
                                                                                                                               lec11/demo-virtual_destructor.cc

                                                                                                                                                                 28 / 48
```

Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition	Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition
Example – Virtual Destructor 3/4	Example – Virtual Destructor 4/4
Using virtual destructor all allocated data are properly released	Without virtual destructor, e.g., class Base {
<pre>cout << "Using Derived " << endl; Derived *object = new Derived(1000000);</pre>	· · · · · · · · · · · · · · · · · · ·
delete object;	<pre>~Base(); // without virtualdestructor };</pre>
<pre>cout << endl;</pre>	<pre>J; Derived *object = new Derived(1000000);</pre>
<pre>cout << "Using Base" << endl;</pre>	delete object;
Base *object = new Derived(1000000);	<pre>Base *object = new Derived(1000000); delate shipet;</pre>
delete object; lec11/demo-virtual_destructor.cc	delete object;
clang++ demo-virtual_destructor.cc && ./a.out	Only both constructors are called, but only destructor of the Base
Using Derived	<pre>class in the second case Base *object = new Derived(1000000);</pre>
Base::Base allocate data	Using Derived
Derived::Derived allocate data2 Derived::~Derived release data2	Base::Base allocate data Derived::Derived allocate data2
Base:: "Base release data	Derived:: "Derived release data2
	Base::~Base release data
Using Base Base::Base allocate data	Using Base
Derived::Derived allocate data2	Base::Base allocate data
Derived:: "Derived release data2	Derived::Derived allocate data2
Base:: "Base release data Both desctructors Derived and Base are called	Base:: "Base release data Only the desctructor of Base is called

Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition	Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition
Inheritance and Composition	Example – Is Cuboid Extended Rectangle ? 1/2
	class <u>Rectangle</u> {
A part of the object oriented programming is the object oriented	public:
design (OOD)	Rectangle(double w, double h) : width(w), height(h) {}
It aims to provide "a plan" how to solve the problem using objects	inline double getWidth(void) const { return width; }
and their relationship	inline double getWidth(Void) const { return height; }
 An important part of the design is identification of the particular objects 	
objects their generalization to the classes 	inline double getDiagonal(void) const
 and also designing a class hierarchy 	
	<pre>return sqrt(width*width + height*height);</pre>
Sometimes, it may be difficult to decides	}
What is the common (general) object and what is the specializa- tion, which is important step for class biography and applying the	
tion, which is important step for class hierarchy and applying the inheritance	protected:
 It may also be questionable when to use composition 	double width;
	double height;
Let show the inheritance on an example of geometrical objects	};

                                  Inheritance
                                             Polymorphism
                                                         Inheritance and Composition
                                                                                Objects and Methods in C++
                                                                                                      Relationship
                                                                                                                  Inheritance
                                                                                                                            Polymorphism
                                                                                                                                        Inheritance and Composition
 Example – Is Cuboid Extended Rectangle? 2/2
                                                                               Example – Inheritance Cuboid Extend Rectangle
                                                                                   Class Cuboid extends the class Rectangle by the depth
   class Cuboid : public Rectangle {
                                                                                        Cuboid inherits data fields width a height
       public:
                                                                                        Cuboid also inherits "getters" getWidth() and getHeight()
          Cuboid(double w, double h, double d) :
                                                                                        Constructor of the Rectangle is called from the Cuboid constructor
              Rectangle(w, h), depth(d) {}
                                                                                   ■ The descendant class Cuboid extends (override) the
          inline double getDepth(void) const { return depth; }
                                                                                     getDiagonal() methods
          inline double getDiagonal(void) const
                                                                                                 It actually uses the method getDiagonal() of the ancestor
          ł
                                                                                                 Rectangle::getDiagonal()
              const double tmp = Rectangle::getDiagonal();
              return sqrt(tmp * tmp + depth * depth);
                                                                                   We create a "specialization" of the Rectangle as an extension
          }
                                                                                     Cuboid class
       protected:
                                                                                                  Is it really a suitable extension?
          double depth;
   };
                                                                                     What is the cuboid area? What is the cuboid circumference?

Objects and Methods in C++ Relationship Inheritance Polymorphism Inheritance and Composition	Topics Discussed
Inheritance and Composition – Pitfalls	
Excessive usage of composition and also inheritance in cases it is	
not needed leads to complicated design	
Watch on literal interpretations of the relationship is-a and has,	Summary of the Lecture
sometimes it is not even about the inheritance, or composition	
E.g., Point2D and Point3D or Circle and Ellipse	
Prefer composition and not the inheritance	
One of the advantages of inheritance is the polymorphism	
Using inheritance violates the encapsulation Especially with the access rights set to the protected
