Effective Software

Lecture 3: Virtual machine, byte-code, (de-)compilers, disassembler, profiling

David Šišlák
david.sislak@fel.cvut.cz

Introduction – Virtual Machine

» Virtual machine execution model

- source code

- compiled VM byte-code

- hybrid run-time environment (platform dependent VM impl.)

    – interpreted byte-code

    – complied assembly-code (native CPU code)

    – automated platform capability optimizations (e.g. use of SIMD)

» byte-code vs. assembly-code

- (+) platform independence (portable) – architecture (RISC/CISC, bits), OS

- (+) reflection – observe, modify own structure at run-time

- (+) small size

- (-) slower execution – interpreted mode, compilation latencies

JAVA Versions

» first release 1996 by Sun Microsystems (later Oracle)

» many different implementations (GNU, IBM, etc.)

» language changes and improvements

- **1.4** (2002) – assert, NIO

- **5.0** (2004) – generics, annotations, auto-boxing, enum, concurrency utils, varargs, foreach, profiling API

- **6** (2005) – basic java script support, performance and GC improvements (G1, compressed pointers), compiler API

- **7** (2011) – invokedynamic, switch strings, auto-closeable, GPU pipeline API

- **8** (2014) – lambda, streams, improved java script support (base on invokedynamic), removed permgen (metaspace/native mem. is used)

- *9 (2017 ?) – Ahead-of-Time Compilation (non-tiered vs. tiered AOT) non-tiered AOT provide predictable performance*

» The Computer Language Benchmarks Game
(*http://benchmarksgame.alioth.debian.org/*)

- 10 different algs. (e.g. DNA manipulation)
How many times slower?

JAVA Virtual Machine – Method Area

» method area shared among all threads

  » class definitions

    » run-time constant pool

    » field and method data

    » byte-code for methods and constructors

    » initialization methods (**<clinit>**, **<init>**)

» native method

  » implementation of native methods

JAVA Virtual Machine - Frame

» **frame**

  » each thread has stack with frames (outside of heap, fixed length)

   StackOverflowError vs. OutOfMemoryError

  » frame is **created** each time method is invoked (**destroyed** after return)

  » frame **size** determined at compile-time (in class file)

  » **variables** (long, double in two)

    » {this} – *instance call only!*

    » {method parameters}

   » {local variables}

  » **operand stack** (any type)

    » LIFO

  » **reference to run-time**
    constant pool (class def)

  » method + class is associated

0 1 2 3 4 5 ...

Array of local variables

Operand stack

Growth

Constant pool

» **stack-oriented** - stack machine model for passing parameters and output

$$(2 + 3) \times 11 + 1$$

Input	2	3	add	11	mul	1	add
Stack		3		11		1	
	2	2	5	5	55	55	56

JAVA Virtual Machine – Opcodes

» **opcode** (1 byte + various parameters):

  » load and store (aload_0, istore, aconst_null, …)

  » arithmetic and logic (ladd, fcmpl, …)

  » type conversion (i2b, d2i, …)

  » object manipulation (new, putfield, getfield, …)

  » stack management (swap, dup2, …)

  » control transfer (ifeq, goto, …)

  » method invocation (invokespecial, areturn, …) – frame manipulation

  » exceptions and monitor concurrency (athrow, monitorenter, …)

» prefix/suffix – i, l, s, b, c, f, d and a (reference)

» variables as registers – e.g. istore_1 (variable 0 is **this** for instance method)

```
mov     %rax,%r8                iconst_0
shl     $0x5,%eax      VS.      istore_3
sub     %r8d,%eax               iload_3
add     %ecx,%eax               bipush      100
inc     %edx
```

JAVA Virtual Machine

» used to implement also other languages than JAVA

 » Erlang -> Erjang

 » JavaScript -> Rhino

 » Python -> Jython

 » Ruby -> Jruby

 » Scala, Clojure – functional programming

 » others

» byte-code is **verified** before executed:

 » branches (jumps) are always to valid locations – only within method

 » any instruction operates on a fixed stack location (helps JIT for registers mapping)

 » data is always initialized and references are always type-safe

 » access to private, package is controlled

```java
public class Employee<Type> {
    private Type data;
    public int id;

    public Employee(Type data, int id) {
        update(data,id);
    }

    private void update(Type data, int id) {
        this.data = data;
        this.id = id;
    }

    public Type employeeData() {
        return data;
    }
}
```

JAVA Virtual Machine – Class File Structure

```
ClassFile {
    u4                          magic;
    u2                          minor_version;
    u2                          major_version;
    u2                          constant_pool_count;
    cp_info                     contant_pool[constant_pool_count - 1];
    u2                          access_flags;
    u2                          this_class;
    u2                          super_class;
    u2                          interfaces_count;
    u2                          interfaces[interfaces_count];
    u2                          fields_count;
    field_info                  fields[fields_count];
    u2                          methods_count;
    method_info                 methods[methods_count];
    u2                          attributes_count;
    attribute_info              attributes[attributes_count];
}
```

```

» **source code compilation** (Source->Bytecode)

    » bytecode is not better than your source code

        » invariants in loop are not removed

    » no optimizations like

        » loop unrolling

        » algebraic simplification

        » strength reduction

» optional external **obfuscator** bytecode optimizations - **ProGuard**

- shrinker – **compact code**, remove dead code
- optimizer
    - modify access pattern (private, static, final)
    - **inline** bytecode

      Test yourself

- obfuscator – renaming, layout changes
- preverifier – ensure class loading

JAVA Virtual Machine – Bytecode Compilation

» **Just-in-time** (JIT)

  » converts bytecode into assembly code in run-time

  » look OpenJDK sources for very detailed information

» **adaptive optimization** (tiered compilation)

  » balance trade-off between JIT and interpreting instructions

  » monitors frequently executed parts "hot spots" including data on caller-callee relationship for virtual method invocation

  » triggers dynamic re-compilation based on current execution profile

  » inline expansion to remove context switching

  » optimize branches

  » can make risky assumption (e.g. skip code) ->

    » unwind to valid state

    » deoptimize previously JITed code even if code is already executed

» Just-in-time (JIT) – usually asynchronous (3 C1, 7 C2 threads for 32 cores)

  » **C1** (client) – much faster than C2

    » simplified inlining, using CPU registry

    » window-based optimization over small set of instructions

    » intrinsic functions with vector operations (Math, arraycopy, …)

  » **C2** (server,d64) – high-end fully optimizing compiler

    » dead code elimination, loop unrolling, loop invariant hoisting, common sub-expression elimination, constant propagation

    » full inlining, full deoptimization (back to level 0)

    » escape analysis, null check elimination,

    » pattern-based loop vectorization and super word packing (**SIMD**)

  » **tiered compilation** – hybrid adapting (since JVM 7, default in JVM8)

  » on-stack replacement (OSR) – optimization during execution

    » start at bytecode jump targets (goto, if_)

```
CompLevel_none                = 0,        // Interpreter
CompLevel_simple              = 1,        // C1
CompLevel_limited_profile     = 2,        // C1, invocation & backedge counters
CompLevel_full_profile        = 3,        // C1, invocation & backedge counters + mdo
CompLevel_full_optimization   = 4,        // C2
```

Assembly Code

» reasons to study **assembly code** (both Java and C/C++)

- educational reasons
  - predict efficient coding techniques
- debugging and verification
  - how well the code looks like
- optimize code
  - for speed
    - avoid poorly compiled patterns
    - data fits into cache
    - predictable branches or no branches
    - use <u>vector programing</u> if possible (**SIMD**)
      » 256bit registers with AVX2 since Intel Sandy Bridge
      » 512bit AVX-512 since Intel Knight Landing (Xeon Phi)
  - for size
    - primarily code cache efficiency

- Instructions
- Data
- Results

stack dealocation, reload register
safepoint poll check

» **safepoint** – Oops in perfectly described state by OopMap (GCmaps)
  - threads are suspended, Oop safely manipulated externally and resumed after
  - in interpreted mode – between any 2 byte codes
  - in C1/C2 compiled – end of all methods (not in-lined), non-counted loop back edge, during JVM run-time call
  - parked, blocked on IO, monitor or lock
  - while running JNI (do not need thread suspension)
  - **global safepoint (all threads)** – stop the world
    – GC, print threads, thread dumps, heap dump, get all stack trace
    – enableBiasedLocking, RevokeBias
    – class redefinition (e.g. instrumentation), debug
  - **local safepoint (just executing thread)**
    – de-optimization, enable/revoke bias locking, OSR

JVM – Time To Safe Point (TTSP)

-XX:+PrintSafepointStatistics -XX:+PrintGCApplicationStoppedTime -XX:PrintSafepointStatisticsCount=1

  0x0000000108a980dc: retq
```

RAX contains return value (primitive int)

Java Virtual Machine – Performance 32 vs 64-bit

» **requires warm-up to utilize benefits of C2 (or C1)**

» compilers cannot do all magic -> **write better algorithms**

» **32-bit vs 64 bits JVMs**

- 32-bit (max ~3GB heap)
  - smaller memory footprint
  - slower long & double operations
- 64-bit max 32GB virtual memory (with default ObjectAlignmentInBytes)
  - faster performance for long&double
  - slight increase of memory footprint
  - compressed OOPs are slightly slower for references upon usage
  - compressed OOPs less memory -> less frequent GC -> faster program
- 64-bit >32GB virtual memory (large heap)
  - fast reference usage
  - wasting a lot of memory (48GB ~32GB with compressed OOPs)

Java Virtual Machine – CPU and Memory Profiling

- » **jvisualvm**
  - JVM monitoring, troubleshooting and profiling tool
  - included in all JDKs
  - profiled thread limit 32
- » **profiling**
  - CPU – time spent in methods
  - memory – usage, allocations
- » **modes**
  - sampling
    - periodic sampling of stacks of running threads to estimate slowest
    - no invocation counts, no 100% accuracy (various sampling errors)
    - no bytecode (& assembly code) modifications
    - 1-2% impact to standard performance
  - tracing (instrumetation)
    - **instrumented bytecode -> affected performance -> affected compiler optimizations**

assembly code of tier 4 – C2 (before there was very complex tier 3)

inlined daysInMonth **rootMethodEntry** tracking

```
# {method} {0x000000012489e838} 'daysInMonth' '(II)Ljava/lang/Integer;' in 'SwitchTest'
# parm0:    rsi       = int
# parm1:    rdx       = int
#           [sp+0x70]  (sp of caller)

JVM – Example 2 – CPU Tracing Outcome

JVM – Example 2 – Profiling Performance

» CPU tracing of **compute** results into **much slower code**
- no object escape from daysInMonth call
- no invariant hoisting
- no strength reduction (full loop remains there)

» object allocation is similar with **traceObjAlloc** injected calls

» **recommended approach**
- do sampling first
- identify performance bottlenecks (where most time is spent)
  - it could be outside of JVM (e.g. latency of external DB, file system)
- focus with tracing just to identified parts

JVM – Java Mission Control

jmc – JRockit JVM, included in commercial JDKs, sampling in Flight recorder
Approach to Performance Testing

» **test real application** – ideally the way it is used

- **microbenchmarks** – measure very small units
  - warm-up – to measure real code, not compilers itself, biased locks
    - keep in mind caching
  - beware of compilers – use results, reordering of operations
  - synchronization – multi-threaded benchmarks
  - vary pre-calculated right parameters affecting complexity – different optimization in reality
- **macrobenchmarks** – measure application input/output
  - least performing component affects the whole application
- **mesobenchmarks** – isolating performance at modular level

» **understand throughput, elapsed and response time**

- outliers can occur – e.g. GC
- use existing generators than writing own

Approach to Performance Testing

» **understand variability** – changes over time

- internal state

- background effects – load, network

- probabilistic analysis – works with uncertainty

» **test early, test often** – ideally part of development cycle

- ideally some properly repeated mesobenchmarking

- automate tests – scripted

- proper test coverage of functionality and inputs

- test on target system – different code on different systems
