Grid and Graph based Path Planning Methods

Jan Faigl

Department of Computer Science

Faculty of Electrical Engineering Czech Technical University in Prague

Lecture 04

B4M36UIR - Artificial Intelligence in Robotics

1 / 49

Overview of the Lecture

Part 1 – Grid and Graph based Path Planning Methods

- Grid-based Planning
- DT for Path Planning
- Graph Search Algorithms
- D* Lite

Path Planning based on Reaction-Diffusion Process Curiosity

Part I

Part 1 – Grid and Graph based Path Planning Methods

Graph Search Algorithms

Grid-based Planning

- A subdivision of \mathcal{C}_{free} into smaller cells
- Grow obstacles can be simplified by growing borders by a diameter of the robot
- Construction of the planning graph
 G = (V, E) for V as a set of cells and
 E as the neighbor-relations

 A grid map can be constructed from the so-called occupancy grid maps

Grid-based Environment Representations

- Hiearchical planning
 - Coarse resolution and re-planning on finer resolution

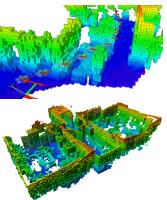

Holte, R. C. et al. (1996): Hierarchical A *: searching abstraction hierarchies efficiently. AAAI.

- Octree can be used for the map representation
- In addition to squared (or rectangular) grid a hexagonal grid can be used
- 3D grid maps octomap

https://octomap.github.io

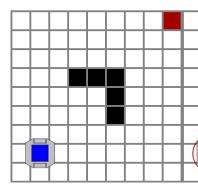

- Memory grows with the size of the environment
- Due to limited resolution it may fail in narrow passages of C_{free}

Example of Simple Grid-based Planning

Wave-front propagation using path simplication

- Initial map with a robot and goal
- Obstacle growing
- Wave-front propagation "flood fill"
- Find a path using a navigation function
- Path simplification
 - "Ray-shooting" technique combined with Bresenham's line algorithm
 - The path is a sequence of "key" cells for avoiding obstacles

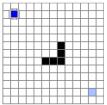

Example – Wave-Front Propagation (Flood Fill)

Jan Faigl, 2017

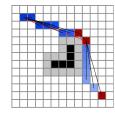

Path Simplification

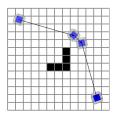

- The initial path is found in a grid using 4-neighborhood
- The rayshoot cast a line into a grid and possible collisions of the robot with obstacles are checked
- The "farthest" cells without collisions are used as "turn" points
- The final path is a sequence of straight line segments

Ray-shooting

Simplified path

Bresenham's Line Algorithm

Filling a grid by a line with avoding float numbers

• A line from (x_0, y_0) to (x_1, y_1) is given by $y = \frac{y_1 - y_0}{x_1 - x_0}(x - x_0) + y_0$

```
CoordsVector& bresenham(const Coords& pt1, const 26
                                                                 int twoDy = 2 * dy;
 1
            Coords& pt2, CoordsVector& line)
                                                        27
                                                                 int twoDyTwoDx = twoDy - 2 * dx; //2*Dy - 2*Dx
                                                        28
                                                                 int e = twoDy - dx; //2*Dy - Dx

Distance Transform based Path Planning

- For a given goal location and grid map compute a navigational function using wave-front algorithm, i.e., a kind of potential field
 - The value of the goal cell is set to 0 and all other free cells are set to some very high value
 - For each free cell compute a number of cells towards the goal cell
 - It uses 8-neighbors and distance is the Euclidean distance of the centers of two cells, i.e., EV=1 for orthogonal cells or $EV = \sqrt{2}$ for diagonal cells
 - The values are iteratively computed until the values are changing
 - The value of the cell c is computed as

$$cost(c) = \min_{i=1}^{8} \left(cost(c_i) + EV_{c_i,c} \right),$$

where c_i is one of the neighboring cells from 8-neighborhood of the cell c

- The algorithm provides a cost map of the path distance from any free cell to the goal cell
- The path is then used following the gradient of the cell cost

Distance Transform Path Planning

Algorithm 1: Distance Transform for Path Planning

```
repeat
```

for
$$y := 1$$
 to $(yMax - 1)$ do
for $x := 1$ to $(xMax - 1)$ do
if not blocked $[x,y]$ then
cell $[x,y] := cost(x, y);$
for $y := (yMax-1)$ downto 1 do
for $x := (xMax-1)$ downto 1 do
if not blocked $[x,y]$ then
cell $[x,y] := cost(x, y);$

until no change;

```

DT Example

 $\delta = 10 \text{ cm}, L = 27.2 \text{ m}$

Graph Search Algorithms

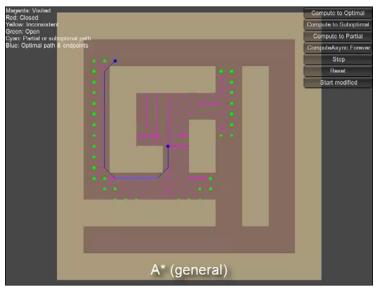

- The grid can be considered as a graph and the path can be found using graph search algorithms
- The search algorithms working on a graph are of general use, e.g.
 - Breadth-first search (BSD)
 - Depth first search (DFS)
 - Dijsktra's algorithm,
 - A* algorithm and its variants
- There can be grid based speedups techniques, e.g.,
 - Jump Search Algorithm (JPS) and JPS+
- There are many search algorithm for on-line search, incremental search and with any-time and real-time properties, e.g.,
 - Lifelong Planning A* (LPA*)

Koenig, S., Likhachev, M. and Furcy, D. (2004): Lifelong Planning A*. AIJ.

B4M36UIR – Lecture 04: Grid and Graph based Path Planning

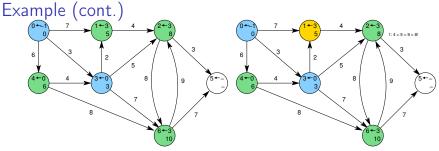

Dijkstra's Algorithm

- Dijsktra's algorithm determines paths as iterative update of the cost of the shortest path to the particular nodes
 - Let start with the initial cell (node) with the cost set to 0 and update all successors
 - Select the node
 - with a path from the initial node
 - and has a lower cost
 - Repeat until there is a reachable node
 - I.e., a node with a path from the initial node
 - has a cost and parent (green nodes).

The cost of nodes can only decrease (edge cost is positive). Therefore, for a node with the currently lowest cost, there cannot be a shorter path from the initial node.

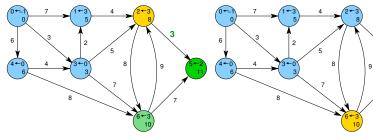

Jan Faigl, 2017

Edsger W. Dijkstra, 1956

node 2 is over the node 3

1: After the expansion, the shortest path to the 2: There is not shorter path to the node 2 over the node 1

3: After the expansion, there is a new path to the node 5 Jan Faigl, 2017

4: The path does not improve for further B4M36UIR - Lecture 04: Grid and Graph based Path Planning

Dijkstra's Algorithm

```
Algorithm 2: Dijkstra's algorithm
Initialize(s<sub>start</sub>);
                                   /* g(s) := \infty; g(s_{start}) := 0 */
PQ.push(s_{start}, g(s_{start}));
while (not PQ.empty?) do
    s := PQ.pop();
    foreach s' \in Succ(s) do
        if s' in PQ then
            if g(s') > g(s) + cost(s, s') then
            | g(s') := g(s) + cost(s, s');
                PQ.update(s', g(s'));
        else if s' \notin CLOSED then
            g(s') := g(s) + cost(s, s');
PQ.push(s', g(s'));
    CLOSED := CLOSED \bigcup \{s\};
```

Dijkstra's Algorithm – Impl.

```
dij->nodes[dij->start_node].cost = 0; // init
1
    void *pq = pq_alloc(dij->num_nodes); // set priority queue
2
3
    int cur label:
    pg_push(pg, dij->start_node, 0);
4
    while ( !pq_is_empty(pq) && pq_pop(pq, &cur_label)) {
5
       node_t *cur = &(dij->nodes[cur_label]); // remember the current node
6
       for (int i = 0; i < cur->edge_count; ++i) { // all edges of cur
7
          edge_t *edge = &(dij->graph->edges[cur->edge_start + i]);
8
          node_t *to = &(dij->nodes[edge->to]);
9
          const int cost = cur->cost + edge->cost;
10
          if (to->cost == -1) { // node to has not been visited
11
             to -> cost = cost;
12
             to->parent = cur_label;
13
             pq_push(pq, edge->to, cost); // put node to the queue
14
          } else if (cost < to->cost) { // node already in the queue
15
             to->cost = cost; // test if the cost can be reduced
16
             to->parent = cur_label; // update the parent node
17
18
             pq_update(pq, edge->to, cost); // update the priority queue
          }
19
20
       } // loop for all edges of the cur node
    } // priority queue empty
21
22
    pq_free(pq); // release memory
```

A* Algorithm

- A* uses a user-defined *h*-values (heuristic) to focus the search Peter Hart, Nils Nilsson, and Bertram Raphael, 1968
 - Prefer expansion of the node *n* with the lowest value

f(n)=g(n)+h(n),

where g(n) is the cost (path length) from the start to n and h(n) is the estimated cost from n to the goal

h-values approximate the goal distance from particular nodes

- Admissibility condition heuristic always underestimate the remaining cost to reach the goal
 - Let $h^*(n)$ be the true cost of the optimal path from n to the goal
 - Then h(n) is admissible if for all n: $h(n) \le h^*(n)$
 - E.g., Euclidean distance is admissible

A straight line will always be the shortest path

Dijkstra's algorithm - h(n) = 0

A* Implementation Notes

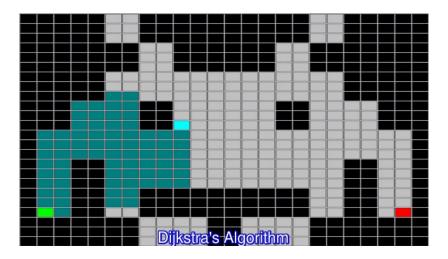

- The most costly operations of A* are
 - Insert and lookup an element in the closed list
 - Insert element and get minimal element (according to f() value) from the open list
- The closed list can be efficiently implemented as a hash set
- The open list is usually implemented as a priority queue, e.g.,
 - Fibonacii heap, binomial heap, k-level bucket
 - **binary heap** is usually sufficient (O(logn))

Forward A*

- 1. Create a search tree and initiate it with the start location
- 2. Select generated but not yet expanded state s with the smallest f-value, f(s) = g(s) + h(s)
- 3. Stop if s is the goal
- 4. Expand the state s
- 5. Goto Step 2

Similar to Dijsktra's algorithm but it used f(s) with heuristic h(s) instead of pure g(s)

Dijsktra's vs A* vs Jump Point Search (JPS)

Theta* – Any-Angle Path Planning Algorithm

- Any-angle path planning algorithms simplify the path during the search
- Theta* is an extension of A* with LineOfSight()

Nash, A., Daniel, K, Koenig, S. and Felner, A. (2007): Theta*: Any-Angle Path Planning on Grids. AAAI.

Algorithm 3: Theta* Any-Angle Planning

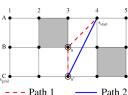

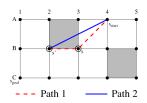

else

/* Path 1 – A* path */ if g(s) + c(s,s') < g(s') then parent(s'):= s; g(s') := g(s) + c(s,s');

Path 2: considers path from start to parent(s) and

http://aigamedev.com/open/tutorials/theta-star-any-angle-paths/

Theta* Any-Angle Path Planning Examples

 Example of found paths by the Theta* algorithm for the same problems as for the DT-based examples on Slide 16

 $\delta = 10$ cm, L = 26.3 m

Both algorithms implemented in C++

 $\delta = 30$ cm, L = 40.3 m

The same path planning problems solved by DT (without path smoothing) have $L_{\delta=10} = 27.2$ m and $L_{\delta=30} = 42.8$ m, while DT seems to be significantly faster

Lazy Theta* – reduces the number of line-of-sight checks Nash, A., Koenig, S. and Tovey, C. (2010): Lazy Theta*: Any-Angle Path Planning and Path Length Analysis in 3D. AAAI.

B4M36UIR - Lecture 04: Grid and Graph based Path Planning

A* Variants – Online Search

• The state space (map) may not be known exactly in advance

- Environment can dynamically change
- True travel costs are experienced during the path execution
- Repeated A* searches can be computationally demanding
- Incremental heuristic search
 - Repeated planning of the path from the current state to the goal
 - Planning under the free-space assumption
 - **Reuse** information from the previous searches (closed list entries):
 - Focused Dynamic A* (D*) h* is based on traversability, it has been used, e.g., for the Mars rover "Opportunity"

Stentz, A. (1995): The Focussed D* Algorithm for Real-Time Replanning. IJCAI.

D* Lite – similar to D*

Koenig, S. and Likhachev, M. (2005): Fast Replanning for Navigation in Unknown Terrain. T-RO.

- Real-Time Heuristic Search
 - Repeated planning with limited look-ahead suboptimal but fast
 - Learning Real-Time A* (LRTA*)

Korf, E. (1990): Real-time heuristic search. JAI

Real-Time Adaptive A* (RTAA*)

Koenig, S. and Likhachev, M. (2006): Real-time adaptive A*. AAMAS.

Jan Faigl, 2017

B4M36UIR – Lecture 04: Grid and Graph based Path Planning

30 / 49

Real-Time Adaptive A* (RTAA*)

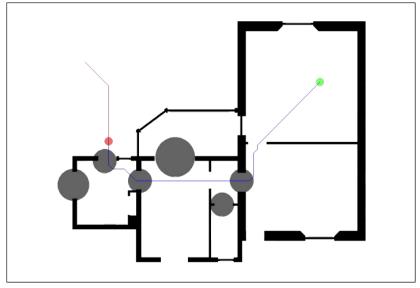

- Execute A* with limited lookahead
- Learns better informed heuristic from the experience, initially h(s), e.g., Euclidean distance
- Look-ahead defines trade-off between optimality and computational cost
 - astar(lookahead)
 A* expansion as far as "lookahead" nodes and it terminates
 with the state s'

while $(s_{curr} \notin GOAL)$ do astar(lookahead); if s' = FAILURE then $\ return FAILURE;$ for all $s \in CLOSED$ do $\ H(s) := g(s') + h(s') - g(s);$ execute(plan); // perform one step

return SUCCESS;

s' is the last state expanded during the previous A^* search

D* Lite – Demo

34 / 49

D* Lite Overview

It is similar to D*, but it is based on Lifelong Planning A*

Koenig, S. and Likhachev, M. (2002): D* Lite. AAAI.

- It searches from the goal node to the start node, i.e., g-values estimate the goal distance
- Store pending nodes in a priority queue
- Process nodes in order of increasing objective function value
- Incrementally repair solution paths when changes occur
- Maintains two estimates of costs per node
 - g the objective function value based on what we know
 - *rhs* one-step lookahead of the objective function value based on what we know
- Consistency
 - Consistent g = rhs
 - Inconsistent $g \neq rhs$
- Inconsistent nodes are stored in the priority queue (open list) for processing

D* Lite: Cost Estimates

rhs of the node *u* is computed based on *g* of its successors in the graph and the transition costs of the edge to those successors

$$rhs(u) = \min_{s' \in Succ(u)} (g(s') + c(u, s'))$$

The key/priority of a node s on the open list is the minimum of g(s) and rhs(s) plus a focusing heuristic h

 $[\min(g(s), rhs(s)) + h(s_{start}, s); \min(g(s), rhs(s))]$

- The first term is used as the primary key
- The second term is used as the secondary key for tie-breaking

D* Lite Algorithm

Main – repeat until the robot reaches the goal (or $g(s_{start}) = \infty$ there is no path)

```
Initialize();
ComputeShortestPath();
while (s_{start} \neq s_{goal}) do
     s_{start} = \operatorname{argmin}_{s' \in Succ(s_{start})}(c(s_{start}, s') + g(s'));
     Move to sstart;
     Scan the graph for changed edge costs;
     if any edge cost changed perform then
          foreach directed edges (u, v) with changed edge costs do
               Update the edge cost c(u, v);
               UpdateVertex(u);
          foreach s \in U do
               U.Update(s, CalculateKey(s));
          ComputeShortestPath();
```

Procedure Initialize

D* Lite Algorithm – ComputeShortestPath()

Procedure UpdateVertex

 $if \ u \neq s_{goal} \ then \ rhs(u) := \min_{s' \in Succ(u)}(c(u, s') + g(s')); \\ if \ u \in U \ then \ U.Remove(u); \\ if \ g(u) \neq rhs(u) \ then \ U.Insert(u, CalculateKey(u));$

Procedure CalculateKey

return $[\min(g(s), rhs(s)) + h(s_{start}, s); \min(g(s), rhs(s))]$

| | | | | | | | | | |
| | | | | | | | | | |

https://github.com/mdeyo/d-star-lite

D* Lite – Comments

- D* Lite works with real valued costs, not only with binary costs (free/obstacle)
- The search can be focused with an admissible heuristic that would be added to the *g* and *rhs* values
- The final version of D* Lite includes further optimization (not shown in the example)
 - Updating the *rhs* value without considering all successors every time
 - Re-focusing the serarch as the robot moves without reordering the entire open list

Reaction-Diffusion Processes Background

- Reaction-Diffusion (RD) models dynamical systems capable to reproduce the autowaves
- Autowaves a class of nonlinear waves that propagate through an active media

At the expense of the energy stored in the medium, e.g., grass combustion.

RD model describes spatio-temporal evolution of two state variables $u = u(\vec{x}, t)$ and $v = v(\vec{x}, t)$ in space \vec{x} and time t

$$\begin{aligned} \dot{u} &= f(u,v) + D_u \triangle u \\ \dot{v} &= g(u,v) + D_v \triangle v \end{aligned} ,$$

where \triangle is the Laplacian.

This RD-based path planning is informative, just for curiosity

Jan Faigl, 2017

B4M36UIR - Lecture 04: Grid and Graph based Path Planning 41 / 49

Reaction-Diffusion Background

FitzHugh-Nagumo (FHN) model

FitzHugh R, Biophysical Journal (1961)

$$\dot{u} = \varepsilon \left(u - u^3 - v + \phi \right) + D_u \triangle u$$

 $\dot{v} = \left(u - \alpha v + \beta \right) + D_v \triangle u$

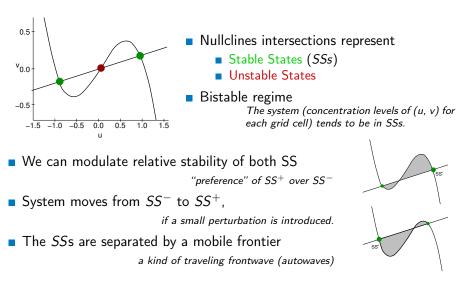

where $\alpha,\beta,\epsilon\text{,}$ and ϕ are parameters of the model.

Dynamics of RD system is determined by the associated nullcline configurations for u=0 and v=0 in the absence of diffusion, i.e.,

$$\begin{aligned} \varepsilon \left(u - u^3 - v + \phi \right) &= 0, \\ \left(u - \alpha v + \beta \right) &= 0, \end{aligned}$$

which have associated geometrical shapes

Nullcline Configurations and Steady States

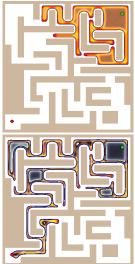

RD-based Path Planning – Computational Model

- Finite difference method on a Cartesian grid with Dirichlet boundary conditions (FTCS) discretization → grid based computation → grid map
- External forcing introducing additional information i.e., constraining concentration levels to some specific values
- Two-phase evolution of the underlying RD model 1. Propagation phase
 - Freespace is set to SS^- and the start location SS^+
 - Parallel propagation of the frontwave with nonannihilation property

Vázquez-Otero and Muñuzuri, CNNA (2010)

- Terminate when the frontwave reaches the goal
- 2. Contraction phase
 - Different nullclines configuration
 - Start and goal positions are forced towards SS^+
 - SS⁻ shrinks until only the path linking the forced points remains
