4 / 36

Jan Faigl, 2017

Grid-based Planning

- A subdivision of C_{free} into smaller cells
- Grow obstacles can be simplified by growing borders by a diameter of the robot
- Construction of the planning graph
 G = (V, E) for V as a set of cells and
 E as the neighbor-relations
 - 4-neighbors and 8-neighbors

 A grid map can be constructed from the so-called occupancy grid maps

Grid-based Environment Representations

- Hiearchical planning
 - Coarse resolution and re-planning on finer resolution
- Octotree can be used for the map representation
- In addition to squared (or rectangular) grid a hexagonal grid can be used
- 3D grid maps octomap

https://octomap.github.io

- Memory grows with the size of the environment
- Due to limited resolution it may fail in narrow passages of C_{free}

- Initial map with a robot and goal
- Obstacle growing
- Wave-front propagation "flood fill"
- Find a path using a navigation function
- Path simplification
 - "Ray-shooting" technique combined with
 - Bresenham's line algorithm

- Find a path using a navigation function
- Path simplification
 - "Ray-shooting" technique combined with
 - Bresenham's line algorithm

Path Simplification

- The initial path is found in a grid using 4-neighbors of a cell
- The rayshoot cast a line into a grid and possible collisions of the robot with obstacles are checked
- The "fartherset" cells without collisions are used as "turn" points
- The final path is a sequence of straight line segments

Obtacle growing, front-wave propagation

Ray-shooting

Simplified path

Bresenham's Line Algorithm

Filling a grid by a line with avoding using float numbers

• A line from (x_0, y_0) to (x_1, y_1) is given by $y = \frac{y_1 - y_0}{x_1 - x_0}(x - x_0) + y_0$

```
CoordsVector& bresenham(const Coords& pt1, const 26
 1
                                                                 int twoDy = 2 * dy;
            Coords& pt2, CoordsVector& line)
                                                        27
                                                                 int twoDyTwoDx = twoDy - 2 * dx; //2*Dy - 2*Dx

Distance Transform based Path Planning

- For a given goal location and grid map compute a navigational function using *frontwave* algorithm, i.e., a kind of *potential field*
 - The value of the goal cell is set to 0 and all other free cells are set to some very high value
 - For each free cell compute a number of cells to towards the goal cell
 - It uses 8-neighbors and distance is the Euclidean distance of the centers of two cells, i.e., EV=1 for orhogonal cells or EV√2 for diagonal cells
 - The values are iteratively computed until the values are changed
 - The value of the cell c is computed as

$$cost(c) = \min_{i=1}^{8} \left(cost(c_i) + EV_{c_i,c} \right),$$

where c_i is one of the neighboring cells from 8-neighborhood of the cell c

- The algorithm provides a cost map of the path distance from any free cell to the goal cell
- The path is than used following the gradient of the cell costs.

Jarvis, R. (2004): Distance Transform Based Visibility Measures for Covert Path Planning in Known but Dynamic Environments

- Grid-based Planning
- DT for Path Planning
- Graph Search Algorithms
- D* Lite

Jan Faigl, 2017

Dijkstra's Algorithm

- The grid can be considered as a graph and the path can be found using graph search algorithms
- Dijsktra's algorithm determines paths as iterative update of the cost of the shortest path to the particular nodes
 - Let start with the initial cell (node) with the cost set to 0 and update all successors
 - Select the node
 - with a path from the initial node
 - and has a lower cost
 - Repeat until there is a reachable node
 - I.e., a node with a path from the initial node
 - has a cost and parent (green nodes).

Edsger W. Dijkstra, 1956

The cost of nodes can only decrease (edge cost is only positive). Therefore, for a node with the currently lowest cost, there cannot be a shorter path from the initial node.

Jan Faigl, 2017

D* Lite

Jan Faigl, 2017

1: After the expansion, the shortest path to the node 2 is over the node 3

2: There is not shorter path to the node 2 over the node 1

3: After the expansion, there is a new path to the node 5

4: The path does not improve for further expansions

A* Algorithm

- A* uses a user-defined *h*-values (heuristic) to focus the search Peter Hart, Nils Nilsson, and Bertram Raphael, 1968
 - Prefer expansion of the node *n* with the lowest value

f(n) = g(n) + h(n),

where g(n) is the cost (path length) from start to n and h(n) is the estimated cost from n to the goal

h-values approximate the goal distance from particular nodes

- Admissibility condition heuristic always underestimate the remaining cost to reach the goal,
 - Let $h^*(n)$ be the true cost of the optimal path from n to the goal
 - Then h(n) is admissible if for all n: $h(n) \le h^*(n)$
 - E.g., Euclidean distance is admissible

A straight line will always be the shortest path

Dijkstra's algorithm - h(n) = 0

A* Implementation Notes

- The most costly operations of A* are
 - Insert and lookup an element in the closed list
 - Insert element and get minimal element (according to f() value) from the open list
- The closed list can be efficiently implemented as a hash set
- The open list is usually implemented as a priority queue, e.g.,
 - Fibonacii heap, binomial hepa, k-level bucket
 - **binary heap** is usually sufficient (O(logn))
- Forward A*
 - 1. Create a search tree and initiate it with the start location
 - 2. Select a generated but not yet expanded state s with the smallest f-value, f(s) = g(s) + h(s)
 - 3. Stop if s is the goal
 - 4. Expand the state s
 - 5. Goto Step 2

Dijsktra's vs A* vs Jump Point Search (JPS)

https://www.youtube.com/watch?v=R0G4Ud081LY

Jump Point Search Algorithm for Grid-based Path Planning

Jump Point Search (JPS) algorithm is based on a macro operator that identifies and selectively expands only certain nodes (jump points)

Harabor, D. and Grastien, A. (2011): Online Graph Pruning for Pathfinding on Grid Maps. AAAI.

- Natural neighbors after neighbor prunning with forced neighbors because of obstacle
- Intermediate nodes on a path connecting two jump points are never expanded

No preprocessing and no memory overheads while it speeds up A*

https://harablog.wordpress.com/2011/09/07/jump-point-search/

Theta* – Any-Angle Path Planning Algorithm

Any-angle path planning algorithms simplify the path during the search

Theta* is an extension of A* with LineOfSight()

Nash, A., Daniel, K, Koenig, S. and Felner, A. (2007): Theta*: Any-Angle Path Planning on Grids. AAAI.

Algorithm 2: Theta* Any-Angle Planning

else

/* Path 1 – A* path */ if g(s) + c(s,s') < g(s') then parent(s'):= s; g(s') := g(s) + c(s,s');

Path 2: considers path from start to parent(s) and from parent(s) to s' if s' has line-of-sight to parent(s)

R R

http://aigamedev.com/open/tutorials/theta-star-any-angle-paths/

Theta* Any-Angle Path Planning Examples

• Example of found paths by the Theta* algorithm for the same problems as for the DT-based examples on Slide 16

Both algorithms implemented in C++

 $\delta = 10$ cm, L = 26.3 m

 $\delta = 30$ cm, L = 40.3 m

The same problems for DT with path smoothing, the path lengths are $L_{\delta=10} = 26.3$ m and $L_{\delta=30} = 40.3$ m, while DT seems to be faster

Lazy Theta* – reduces the number of line-of-sight checks Nash, A., Koenig, S. and Tovey, C. (2010): Lazy Theta*: Any-Angle Path Planning and Path Length Analysis in 3D. AAAI.

B4M36UIR - Lecture 04: Grid and Graph based Path Planning

A* Variants – Online Search

- The state space (map) may not be known exactly in advance
 - Environment can dynamically change
 - True travel costs are experienced during the path execution
- Repeated A* searches can be computationally demanding
- Incremental heuristic search
 - Repeated planning of the path from the current state to the goal
 - Planning under the free-space assumption
 - **Reuse** information from the previous searches (closed list entries):
 - Focused Dynamic A* (D*) h* is based on traversability, used for Mars Rover "Opportunity"

Stentz, A. (1995): The Focussed D* Algorithm for Real-Time Replanning. IJCAI.

D* Lite – similar to D*

Koenig, S. and Likhachev, M. (2005): Fast Replanning for Navigation in Unknown Terrain. T-RO.

Real-Time Heuristic Search

- Repeated planning with limited look-ahead suboptimal but fast
 - Learning Real-Time A* (LRTA*)

Korf, E. (1990): Real-time heuristic search. JAI

Real-Time Adaptive A* (RTAA*)

Koenig, S. and Likhachev, M. (2006): Real-time adaptive A*. AAMAS.

Real-Time Adaptive A* (RTAA*)

- Execute A* with limited lookahead
- Learns better informed heuristic from the experience, initially h(s), e.g., Euclidean distance
- Look-ahead defines trade-off between optimality and computational cost
 - astar(lookahead)
 A* expansion as far as "lookahead" nodes and it terminates
 with the state s'

while $(s_{curr} \notin GOAL)$ do astar(lookahead); if s' = FAILURE then $\ return FAILURE;$ for all $s \in CLOSED$ do $\ H(s) := g(s') + h(s') - g(s);$ execute(plan); // perform one step

return SUCCESS;

s' is the last state expanded during the previous A^* search

D* Lite – Demo

https://www.youtube.com/watch?v=X5a149nSE9s

D* Lite Overview

It is similar to D*, but it is based on Lifelong Planning A*

Koenig, S. and Likhachev, M. (2002): D* Lite. AAAI.

- It searches from the goal node to the start node, i.e., g-values estimate the goal distance
- Store pending nodes in a priority queue
- Process nodes in order of increasing objective function value
- Incrementally repair solution paths when changes occur
- Maintains two estimates of costs per node
 - g the objective function value based on what we know
 - *rhs* one-step lookahead of the objective function value based on what we know
- Consistency
 - Consistent g = rhs
 - Inconsistent $g \neq rhs$
- Inconsistent nodes are stored in the priority queue (open list) for processing

Jan Faigl, 2017

D* Lite: Cost Estimates

rhs of the node *u* is computed based on *g* of its successors in the graph and the transition costs of the edge to those successors

$$rhs(u) = \min_{s' \in Succ(u)} (c(u, s') + g(s'))$$

The key/priority of a node s in the open list is the minimum of g(s) and rhs(s) plus a focusing heuristic h

 $[\min(g(s), rhs(s)) + h(s_{start}, s); \min(g(s), rhs(s))]$

The first term is used as the primary key

The second term is used for as the secondary key for tie-breaking

D* Lite Algorithm

Repeat until the robot reaches the goal $(or g(s_{start}) = \infty \text{ there is no path})$

```
U = 0;
foreach s \in S do rhs(s) := g(s) := \infty;
rhs(s_{roal} := 0;
U.Insert(sgoal, CalculateKey(sgoal));
/* end initialization */;
ComputeShortestPath();
while (s_{start} \neq s_{goal}) do
    s_{start} = \operatorname{argmin}_{s' \in Succ(s_{start})}(c(s_{start}, s') + g(s'));
Move to sstart;
Scan the graph for changed edge costs;
if any edge cost changed perform then
     foreach directed edges (u, v) with changed edge costs do
          Update the edge cost c(u, v);
          UpdateVertex(u);
     foreach s \in U do
          U.Update(s, CalculateKey(s));
     ComputeShortestPath();
```

D* Lite Algorithm – ComputeShortestPath()

```
Procedure ComputeShortestPath

while U.TopKey() < CalculateKey(s<sub>start</sub>) OR rhs(s<sub>start</sub>) \neq g(s<sub>start</sub>) do

u := \bigcup.Pop();

if g(u) > rhs(u) then

g(u) := rhs(u);

foreach s \in Pred(u) do UpdateVertex(s);

else

g(u) := \infty;

foreach s \in Pred(u) \bigcup \{u\} do UpdateVertex(s);
```

Procedure UpdateVertex

if $u \neq s_{goal}$ then $rhs(u) := \min_{s' \in Succ(u)}(c(u, s') + g(s'));$ if $u \in U$ then U.Remove(u); if $g(u) \neq rhs(u)$ then U.Insert(u, CalculateKey(u));

Procedure CalculateKey return $[min(g(s), rhs(s)) + h(s_{start}, s); min(g(s), rhs(s))]$

Summary of the Lecture
