

#### Lecture 2 – Program flow, Conditionals, Loops https://cw.fel.cvut.cz/wiki/courses/be5b33prg/start

# Michal Reinštein

Czech Technical University in Prague, Faculty of Electrical Engineering, Dept. of Cybernetics, Center for Machine Perception <u>http://cmp.felk.cvut.cz/~reinsmic/</u> reinstein.michal@fel.cvut.cz

- Problem formulation (input / output)
- Formalism (math?)
- Algorithm (the idea!)
- Implementation (engineering)
- Testing (are we good?)

# **DATA TYPES**

- Integers (int)
- Strings (str)

• Float (float)

- 1, 10, 124 "Hello, World!" 1.0, 9.999
- Strings in Python can be enclosed in either single quotes (') or double quotes ("), or three of each ("' or """)

# VARIABLES

- We use variables to remember things!
- The assignment statement gives a value to a variable
- Do not confuse = and == !
  - = is **assignment** token such that *name\_of\_variable* = *value*
  - == is operator to test equality
- Key property of a variable that we can change its value
- Naming convention: with freedom comes responsibility!

### VARIABLES

5

- The longer life the longer name: <a href="mailto:very\_long\_name\_of\_my\_var">very\_long\_name\_of\_my\_var</a>
- The more important the longer name
- Meaningful name does not add the meaning just by itself, the code must do this!
- Illegal name causes a syntax error
- Capitals: Variable vs variable

## **KEYWORDS**

m	р

and	as	assert	break	class	continue
def	del	elif	else	except	exec
finally	for	from	global	if	import
in	is	lambda	nonlocal	not	or
pass	raise	return	try	while	with
yield	True	False	None		

- Python keywords have special purpose
- Always choose names meaningful to human readers
- Use comments (#) and blank lines to improve readability

# **BUILT-IN FUNCTIONS**

7

		<b>Built-in Functions</b>		
abs()	dict()	help()	min()	<pre>setattr()</pre>
all()	dir()	hex()	next()	<pre>slice()</pre>
any()	divmod()	id()	object()	<pre>sorted()</pre>
ascii()	<pre>enumerate()</pre>	<pre>input()</pre>	oct()	<pre>staticmethod()</pre>
bin()	eval()	int()	open()	str()
bool()	exec()	<pre>isinstance()</pre>	ord()	sum()
<pre>bytearray()</pre>	filter()	<pre>issubclass()</pre>	pow()	<pre>super()</pre>
bytes()	float()	iter()	<pre>print()</pre>	<pre>tuple()</pre>
callable()	<pre>format()</pre>	len()	<pre>property()</pre>	type()
chr()	<pre>frozenset()</pre>	list()	range()	vars()
<pre>classmethod()</pre>	getattr()	locals()	repr()	zip()
<pre>compile()</pre>	globals()	map()	reversed()	<pre>import()</pre>
<pre>complex()</pre>	hasattr()	max()	round()	
delattr()	hash()	<pre>memoryview()</pre>	set()	

- Built-in functions have special purpose
- Study <u>https://docs.python.org/3.4/library/functions.html</u>

source <a href="http://openbookproject.net/thinkcs/python/english3e/variables\_expressions\_statements.html">http://openbookproject.net/thinkcs/python/english3e/variables\_expressions\_statements.html</a>

- OPERAND OPERATOR OPERAND
- Operators are **special tokens** that represent computations like addition, subtraction, multiplication, division etc
- The values the operator uses are called operands
- When a variable name appears in the place of an operand, it is replaced with its value before the operation is performed
- Division / vs *floor* division //

## **TYPE CONVERSION**

- Functions, int(), float() and str() convert their arguments into types int, float and str respectively.
- The type converter float() can turn an integer, a float, or a syntactically legal string into a float
- The type converter str() turns its argument into a string
- One symbol can have different meaning depending on the data type(s) - try & explore & understand

- Evaluation depends on the rules of precedence:
- 1. Parentheses (for order, readability)
- 2. Exponentiation
- 3. Multiplication and Division
- 4. Addition and Subtraction
- Order left-to-right evaluation on the same level, with the exception of exponentiation (\*\*)

# **OPERATIONS ON STRINGS**

# Ennon

11

	<pre>&gt;&gt;&gt; "Hello" / 123 &gt;&gt;&gt; message * "Hello" &gt;&gt;&gt; "15" + 2</pre>	# Error # Error # Error	
Python Console			
<pre>/opt/local/bin/python3.6./Applications/F Python 3.6.3 (default, Oct 5 2017, 23:3 In [2]:.name.=."Bob" In [3]:.age.=.17 In [4]:.description.=."My.name.is.".+.nam In [5]:.print(description) My.name.is.Boband.my.age.is.17 In [6]: </pre>	PyCharm.app/Contents/helpers/pyc 34:28) me.+."and.my.age.is."+.str(age)	Special Variables          Image: Special Variables         Image: Special Variables         Image: Str} "         Image: Str} Special Variables         Image: Str} Special Variables <td></td>	

- You cannot perform mathematical operations on strings, even if the strings look like numbers
- The + operator represents concatenation, not addition
- The \* operator also works on strings; it performs repetition (one of the operands has to be a string; the other has to be an integer)

### INPUT

12

Pyth	on Console	
G ■ × > 2	<pre>/opt/local/bin/python3.6./Applications/PyCharm.app/Contents/he Python 3.6.3 (default, Oct 5 2017, 23:34:28) In[2]:.response.=.input("What.is.your.radius?.")</pre>	Special Variables          Image: Special Variables
• 		R response = {str} '11'

• Built-in function to get input from a user:

#### input("Message to the user!")

- User input is stored as string
- Combine with type conversion

## **COMPOSITION**

13

- Combination of the elements of a program: variables, expressions, statements, and function calls
- One of the most useful features of programming languages
- Take small building blocks and compose them into larger chunks

- The modulus operator works on integers (integer expressions)
- Definition: modulus is the remainder when the first number is divided by the second
- Modulus operator is a percent sign %
- Syntax is the same as for other operators
- The same precedence as the multiplication operator

## THE FOR LOOP

15

Python Console /opt/local/bin/python3.6 /Applications/PyCharm.app/Contents/helpers/pydev/pydevconsol Special Variables Python 3.6.3 (default, Oct 5 2017, 23:34:28) :.for.friend.in.["Joe",."Zoe",."Brad",."Angelina",."Zuki",."Thandi",."Paris"]: invite = "Hi.".+.friend.+."...Please.come.to.my.party.on.Saturday!" print(invite) I friend = {str} 'Paris' Hi Joe. Please come to my party on Saturday! Hi Zoe. Please come to my party on Saturday! III invite = {str} 'Hi Paris. Please come to my party on Saturday!' Hi Brad. Please come to my party on Saturday! Hi Angelina. .. Please come to my party on Saturday! Hi Zuki. Please come to my party on Saturday! 📨 Hi Thandi. Please come to my party on Saturday! Hi Paris. Please come to my party on Saturday!

- The variable friend at line 1 is the loop variable
- Lines 2 and 3 are the loop body
- The loop body is always indented
- The <u>indentation</u> determines exactly what <u>statements</u> are "in the body of the loop"
- At the end of each execution of the body of the loop, Python returns to the for statement, to see if there are more items to be handled, and to assign the next one to the loop variable

source http://openbookproject.net/thinkcs/python/english3e/hello\_little\_turtles.html

# THE FOR LOOP

On each iteration or pass of the loop:

- Check to see if there are still more items to be processed
- If there are none left (the terminating condition of the loop) the loop has finished
- If there are items still to be processed, the loop variable is updated to refer to the next item in the list
- Program execution continues at the next statement after the loop body
- To explore: early break, or for else loop

16

- Control flow (control of the flow of execution of the program)
- As program executes, the interpreter always keeps track of which statement is about to be executed
- Control flow until now has been strictly top to bottom, one statement at a time, the for loop changes this!

source http://openbookproject.net/thinkcs/python/english3e/hello\_little\_turtles.html

D

```
>>> type(True)
<class 'bool'>
>>> type(true)
Traceback (most recent call last):
   File "<interactive input>", line 1, in <module>
NameError: name 'true' is not defined
```

- Test conditions and change the program behavior depending on the outcome of the tests
- Boolean value is either True or False
- Named after the British mathematician, George Boole, who first formulated Boolean algebra

m	р

 $\rightarrow$  5 == (3 + 2) # Is five equal 5 to the result of 3 + 2? True  $\rightarrow$  5 == 6 False >>> j = "hel" >>> j + "lo" == "hello" True # Produce True if ... x is equal to y  $\mathbf{x} == \mathbf{y}$ # ... x is not equal to y  $\mathbf{x} = \mathbf{y}$ # ... x is greater than y x > y # ... x is less than y x < y # ... x is greater than or equal to y x >= y

• Boolean expression is an expression that evaluates to produce a result which is a Boolean value

# ... x is less than or equal to y

• Six common comparison operators which all produce a bool result (different from the mathematical symbols)

source http://openbookproject.net/thinkcs/python/english3e/conditionals.html

 $\mathbf{X} \leq \mathbf{V}$ 

#### **LOGICAL OPERATORS**

20

Pytho	on Console	<b>☆</b> - ≟
Ċ	<pre>/opt/local/bin/python3.6./Applications/PyCharm.app/Contents/helpers/pydev/pydevconsole.py Python 3.6.3 (default, Oct 5 2017, 23:34:28) In[2]:.n.=.4#.divisible.by.2:.print(n.%.2.==.0.or.n.%.3.==.0)</pre>	. 52255 . 52
× •	True In[3]:.n.=.6#.divisible.by.2.and.3 :.print(n.%.2.==.0.or.n.%.3.==.0)	
	True In[4]:.n.=.5#.not.divisible.by.2.or.3 print(n.%.2.==.0.or.n.%.3.==.0)  False	

- three logical operators, and, or, and not, that allow to build more complex expressions from simple Boolean expressions
- semantics (meaning) of these operators is similar to natural language equivalent

#### **TRUTH TABLES**

#### **Short-circuit evaluation:**

- OR if the expression on the left of the operator yields True, Python does not evaluate the expression on the right
- AND if the expression on the left yields False, Python does not evaluate the expression on the right.
- Truth table list of all the possible inputs to give the results for the logical operators

#### **BOOLEAN ALGEBRA**

22

```
n * 0 == 0
```

```
x and False == False
False and x == False
y and x == x and y
x and True == x
True and x == x
x and x == x
```

```
x or False == x
False or x == x
y or x == x or y
x or True == True
True or x == True
x or x == x
```

not (not x) == x

source http://openbookproject.net/thinkcs/python/english3e/conditionals.html

source http://openbookproject.net/thinkcs/python/english3e/conditionals.html

source http://openbookproject.net/thinkcs/python/english3e/conditionals.html

# **CONDITIONAL EXECUTION**

25

- Condition chaining
   IF ELIF ELSE
- Recommendation: handle all distinctive options by separate condition, use else to handle all other

source http://openbookproject.net/thinkcs/python/english3e/conditionals.html

# Assume x is an int here **if** 0 < x: 1 2 if x < 10: print("x is a positive single digit.") 3 False True x < y True False statements a x > ystatements\_c statements b

- Nesting conditions builds hierarchy of decisions (decision trees)
- Nesting may reduce readability and clarity

source http://openbookproject.net/thinkcs/python/english3e/conditionals.html

```
for n in range(2, 10):
    for x in range(2, n):
        if n % x == 0:
            print(n, 'equals', x, '*', n/x)
            break
```

```
for n in range(2, 10):
    for x in range(2, n):
        if n % x == 0:
            print( n, 'equals', x, '*', n/x)
            break
else:
        # loop fell through without finding a factor
        print(n, 'is a prime number')
```

- Early return / early break
- Can be used to speed-up code execution
- Special condition: FOR ELSE

source <a href="http://book.pythontips.com/en/latest/for\_-\_else.html">http://book.pythontips.com/en/latest/for\_-\_else.html</a>

operator	logical opposite	
==	!=	
!=	== 1	<pre>if not (age &gt;= 17):     print("Hey, you're too young to get a driving licence!")</pre>
<	>=	
<=	>	
>	<= 1	age < 17:
>=	< 2	<pre>print("Hey, you're too young to get a driving licence!")</pre>

- Each of the six relational operators has a logical opposite
- Recommendation: not operators may reduce readability, use logical opposites instead

# **DE MORGAN'S LAWS**

29

if not ((sword\_charge >= 0.90) and (shield\_energy >= 100)):
 print("Your attack has no effect, the dragon fries you to a crisp!")
else:
 print("The dragon crumples in a heap. You rescue the gorgeous princess!")

- De Morgan's laws rules allow the expression of conjunctions and disjunctions in terms of each other via negation
- <u>Example</u>: suppose we can slay the dragon only if our magic sword is charged to 90% or higher and we have 100 or more energy units in our protective shield

4

30

- if (sword\_charge < 0.90) or (shield\_energy < 100):
   print("Your attack has no effect, the dragon fries you to a crisp!")
  else:
   print("The dragon crumples in a heap. You rescue the gorgeous princess!")
  if (sword\_charge >= 0.90) and (shield\_energy >= 100):
   print("The dragon crumples in a heap. You rescue the gorgeous princess!")
  - else:
     print("Your attack has no effect, the dragon fries you to a crisp!")

• <u>Example</u>: suppose we can slay the dragon only if our magic sword is charged to 90% or higher and we have 100 or more energy units in our protective shield

(not (p and q)) or r p q r F FF ? F FΤ ? ? F TF ТТ ? F F F ? Т TFT ? ? ΤF Т ттт ?

#### • Example: complete the table ..
