Department of Cybernetics
Faculty of Electrical Engineering, Czech Technical University in Prague

April 23, 2024

(Re-)introduction uncertainty/probability

- ► Markov Decision Processes (MDP)/RL uncertainty about outcome of actions
 - ▶ Sequential decisions (robot/agent goes from s_0 to s_G)
 - ightharpoons $\pi: \mathcal{S} \to \mathcal{A}$
- Now: uncertainty associated with states
 - ▶ Different states may have different prior probabilities.
 - ▶ The states $s \in S$ are not directly observable
 - ▶ They need to be inferred from features $x \in \mathcal{X}$
 - ightharpoonup Single (repeated) decision $\delta: \mathcal{X} \to \mathcal{S}$

2 / 24

Notes -

Just a reminder: MDPs, value iteration and policy iteration methods. In RL: temporal difference learning. Now, strictly speaking, we are interested in single decision. Due to its stochastic nature, we understand that anything can happen and we are seeking optimality in a statistical sense - what is the outcome of the decision when repeated.

(Re-)introduction uncertainty/probability

Due to its stochastic nature, we understand that anything can happen and we are seeking optimality in a statistical sense - what is the outcome of the decision when repeated.

Known about HIV testing: HIV test falsely positive only in 1 case out of 1000. A doctor calls: "Your HIV test is positive, 999/1000 you will die in 10 years. I'm sorry . . . ". Insurance company does not want to insure a married couple.

- ► Was the doctor right?
- ► Was the insurance company rational?
- $\mathcal{S} = \{ \mathsf{healthy}, \mathsf{infected} \}, \ \mathcal{X} = \{ \mathsf{positive_test}, \mathsf{negative_test} \}$

3 / 24

Known about HIV testing: HIV test falsely positive only in 1 case out of 1000. A doctor calls: "Your HIV test is positive, 999/1000 you will die in 10 years. I'm sorry ...". Insurance company does not want to insure a married couple.

- ► Was the doctor right?
- ► Was the insurance company rational?

 $\mathcal{S} = \{ \mathsf{healthy}, \mathsf{infected} \}, \; \mathcal{X} = \{ \mathsf{positive_test}, \mathsf{negative_test} \}$

3 / 24

Known about HIV testing: HIV test falsely positive only in 1 case out of 1000. A doctor calls: "Your HIV test is positive, 999/1000 you will die in 10 years. I'm sorry . . . ". Insurance company does not want to insure a married couple.

- ► Was the doctor right?
- ► Was the insurance company rational?

 $S = \{\text{healthy}, \text{infected}\}, \ \mathcal{X} = \{\text{positive_test}, \text{negative_test}\}$

3 / 24

Known about HIV testing: HIV test falsely positive only in 1 case out of 1000.

A doctor calls: "Your HIV test is positive, 999/1000 you will die in 10 years. I'm sorry ...". Insurance company does not want to insure a married couple.

- ► Was the doctor right?
- ▶ Was the insurance company rational?

 $S = \{\text{healthy}, \text{infected}\}, \ \mathcal{X} = \{\text{positive_test}, \text{negative_test}\}$

What is the probability the man is infected?

- A: $\frac{1}{1000}$
- B: $\frac{999}{1000}$
- C: Don't know yet, more info needed, but less than $\frac{1}{2}$
- D: Don't know yet, more info needed, but more than $\frac{1}{2}$

- ▶ Robbery, LA 1964, fuzzy evidence of the offenders:
 - ▶ female, around 65 kg
 - wearing something dark
 - hair of light color, between light and dark blond, in a ponytail
- At the same time, additional evidence close to the crime scene:
 - loud scream, yelling, looking at the this direction
 - . . .
 - a woman sitting into a yellow car
 - car starts immediately and passes close to the additional witness
 - ▶ a black man with beard and moustache was driving
- No more evidence
- ► Testimony of both the victim and the witness not unambiguous (didn't recognize suspects)
- ► Still, the suspects were sentenced to jail.

Notes

Wrong use of independence assumption:

```
P(\text{yellow car}) = 1/10
P(\text{man with moustache}) = 1/4
P(\text{black man with beard}) = 1/10
P(\text{woman with pony tail}) = 1/10
P(\text{woman blond hair}) = 1/3
P(\text{mix race pair in a car}) = 1/1000
```

4 / 24

and mistakenly confusing probability

P(randomly selected pair matches discussed characteristics)

giving P=1/12000000. Think about total California population.

with the needed conditional probability: P(a pair matching characteristics is guilty)

"The court noted that the correct statistical inference would be the probability that no other couple who could have committed the robbery had the same traits as the defendants given that at least one couple had the identified traits. The court noted, in an appendix to its decision, that using this correct statistical inference, even if the prosecutor's statistics were all correct and independent as he assumed, the probability that the defendants were innocent would be over 40%." https://en.wikipedia.org/wiki/People_v._Collins

P(yellow car) = 1/10 P(man with moustache) = 1/4 P(black man with beard) = 1/10 P(woman with pony tail) = 1/10 P(woman blond hair) = 1/3 P(mix race pair in a car) = 1/1000

$$P(?) = \frac{1}{10.0000000}$$

What probability?

A Convicted pair not guilty

B A randomly selected pair matches characteristics.

C Some other

P(yellow car) = 1/10 P(man with moustache) = 1/4 P(black man with beard) = 1/10 P(woman with pony tail) = 1/10 P(woman blond hair) = 1/3 P(mix race pair in a car) = 1/1000

Assume (wrong!) mutual indepedence:

$$P(?) = \frac{1}{12,000,000}$$

What probability?

A Convicted pair not guilty

B A randomly selected pair matches characteristics.

C Some other

P(yellow car) = 1/10 P(man with moustache) = 1/4 P(black man with beard) = 1/10 P(woman with pony tail) = 1/10 P(woman blond hair) = 1/3 P(mix race pair in a car) = 1/1000

Assume (wrong!) mutual indepedence:

$$P(?) = \frac{1}{12,000,000}$$

What probability?

- A Convicted pair not guilty.
- B A randomly selected pair matches characteristics.
- C Some other.

Computed (wrongly):

$$P_r = P(\text{randomly selected pair matches discussed characteristics}) = \frac{1}{12,000,000}$$

Judge needs:

P(a pair matching characteristics is guilty) =?

 $P(\text{randomly selected pair does not match}) = 1 - P_r$ possible/existing pairs in California . . . N

P(pair will never appear in N) = P(NA) = (1)

 $P(\mathsf{pair} \; \mathsf{will} \; \mathsf{appear} \; \mathsf{at} \; \mathsf{least} \; \mathsf{once} \; \mathsf{in} \; N) = P(ALO) = 1 - P(NA) = 1 - (1 - P_r)^N$

 $P(\mathsf{pair} \; \mathsf{will} \; \mathsf{appear} \; \mathsf{exactly} \; \mathsf{once} \; \mathsf{in} \; N) = P(EO) = \mathit{NP}_r (1-P_r)^{N-1}$

P(pair will appear more than once in N) = P(MTO) = P(ALO) - P(EO)

$$P(MTO|ALO) = \frac{P(MTO,ALO)}{P(ALO)} = \frac{P(MTO)}{P(ALO)}$$

$$P(MTO|ALO) = \frac{1 - (1 - P_r)^N - NP_r(1 - P_r)^{N-1}}{1 - (1 - P_r)^N}$$

6 / 24

Computed (wrongly):

$$P_r = P(\text{randomly selected pair matches discussed characteristics}) = \frac{1}{12,000,000}$$

Judge needs:

$$P(a pair matching characteristics is guilty) =?$$

$$P(\text{randomly selected pair does not match}) = 1 - P_{\text{randomly selected pair does not match}}$$

possible/existing pairs in California . . . N

 $P(\text{pair will never appear in } N) = P(NA) = (1 - P_r)^N$

P(pair will appear exactly once in $N)=P(\mathit{EO})=\mathit{NP}_r(1-P_r)^{N-1}$

P(pair will appear more than once in N) = P(MTO) = P(ALO) - P(EO)

$$P(MTO|ALO) = \frac{P(MTO,ALO)}{P(ALO)} = \frac{P(MTO)}{P(ALO)}$$

Notes

Probabilistic Classification

8 / 24

Classification example: What's the fish?

- ► Factory for fish processing
- \triangleright 2 classes $s_{1,2}$:
 - salmon
 - sea bass
- Features \vec{x} : length, width, lightness etc. from a camera

9 / 24

- Sea (European) bass, https://en.wikipedia.org/wiki/European_bass. (In Czech it is Mořčák evropský or Mořský vlk.)
- Salmon, https://en.wikipedia.org/wiki/Salmon. (losos in Czech)

Fish – classification using probability

$$posterior = \frac{\textit{likelihood} \times \textit{prior}}{\textit{evidence}}$$

- Notation for classification problem
 - ▶ Classes $s_j \in \mathcal{S}$ (e.g., salmon, sea bass)
 - Features $x_i \in \mathcal{X}$ or feature vectors $(\vec{x_i})$ (also called attributes)
- ightharpoonup Optimal classification of \vec{x}

$$\delta^*(\vec{x}) = \arg\max_i P(s_j|\vec{x})$$

- We thus choose the most probable class for a given feature vector
- ▶ Both likelihood and prior are taken into account recall Bayes rule:

$$P(s_j|\vec{x}) = \frac{P(\vec{x}|s_j)P(s_j)}{P(\vec{x})}$$

► Can we do (classify) better?

10 / 24

Notes -

Assuming we know the true $P(\vec{x}|s_i), P(s_i), P(\vec{x})$ we cannot do better! Bayesian classification is optimal!

Fish – classification using probability

$$posterior = \frac{\textit{likelihood} \times \textit{prior}}{\textit{evidence}}$$

- ► Notation for classification problem
 - ▶ Classes $s_i \in \mathcal{S}$ (e.g., salmon, sea bass)

Can we do (classify) better?

10 / 24

Notes -

Assuming we know the true $P(\vec{x}|s_i), P(s_i), P(\vec{x})$ we cannot do better! Bayesian classification is optimal!

- ► An important feature of intelligent systems
 - make the best possible decision
 - in uncertain conditions
- **Example**: Take a tram OR subway from A to B?
 - Tram: timetables imply a quicker route, but adherence uncertain
 - Subway: longer route, but adherence almost certain.
- **Example**: where to route a letter with this ZIP?

- **15700?** 15706? 15200? 15206?
- ▶ What is the optimal decision
- What is the cost of the decision? What is the associated loss?
- ▶ What is the relation between loss and utility ?

Notes -

There are *costs* associated with a decision. E.g. at fish packing plant, customers may not mind so much if some pieces of salmon end up in sea bass cans, but they will be protesting if the opposite happens. So making an error "one way" has higher cost than "the other way". This impacts where decision boundaries for classification should optimally be drawn.

The decision loss can be seen as counterpart of the utility. We want either maximize utility or minimize loss. In machine learing and pattern recognition community, the term loss is used much more frequently.

- ► An important feature of intelligent systems

Notes -

There are *costs* associated with a decision. E.g. at fish packing plant, customers may not mind so much if some pieces of salmon end up in sea bass cans, but they will be protesting if the opposite happens. So making an error "one way" has higher cost than "the other way". This impacts where decision boundaries for classification should optimally be drawn.

The decision loss can be seen as counterpart of the utility. We want either maximize utility or minimize loss. In machine learning and pattern recognition community, the term loss is used much more frequently.

- ► An important feature of intelligent systems
 - make the best possible decision
 - in uncertain conditions
- **Example**: Take a tram OR subway from A to B?
 - ▶ Tram: timetables imply a quicker route, but adherence uncertain.
 - ► Subway: longer route, but adherence almost certain.
- **Example**: where to route a letter with this ZIP?

- ► 15700? 15706? 15200? 15206?
- ► What is the optimal decision ?
- ▶ What is the cost of the decision? What is the associated loss ?
- ▶ What is the relation between loss and utility

Notes —

There are *costs* associated with a decision. E.g. at fish packing plant, customers may not mind so much if some pieces of salmon end up in sea bass cans, but they will be protesting if the opposite happens. So making an error "one way" has higher cost than "the other way". This impacts where decision boundaries for classification should optimally be drawn.

The decision loss can be seen as counterpart of the utility. We want either maximize utility or minimize loss. In machine learning and pattern recognition community, the term loss is used much more frequently.

Decision making under uncertainty

- ► An important feature of intelligent systems
 - make the best possible decision
 - in uncertain conditions
- **Example**: Take a tram OR subway from A to B?
 - ► Tram: timetables imply a quicker route, but adherence uncertain.
 - ► Subway: longer route, but adherence almost certain.
- **Example**: where to route a letter with this ZIP?

- **15700?** 15706? 15200? 15206?
- ► What is the optimal decision ?
- ▶ What is the cost of the decision? What is the associated loss ?
- ▶ What is the relation between loss and utility ?

Notes -

There are *costs* associated with a decision. E.g. at fish packing plant, customers may not mind so much if some pieces of salmon end up in sea bass cans, but they will be protesting if the opposite happens. So making an error "one way" has higher cost than "the other way". This impacts where decision boundaries for classification should optimally be drawn.

The decision loss can be seen as counterpart of the utility. We want either maximize utility or minimize loss. In machine learning and pattern recognition community, the term loss is used much more frequently.

Introducing decision loss: Coin recognition

- ▶ $s \in \{1, 2, 5, 10, 20, 50\}$ state the true value
- $ightharpoonup x \in \{0.0, 0.1, \cdots, 9.9\}[g]$ measurement, observation
- \triangleright P(s,x) joint probability
- \rightarrow $d \in \{1, 2, 5, 10, 20, 50\}$ decision, result of the algorithm

Notes -

P(s,x) think about an Oracle for the moment, we will discuss it more later We assume 100 possible measurements $x \in \{0.0, 0.1, \dots, 9.9\}$

- ▶ $s \in \{1, 2, 5, 10, 20, 50\}$ state the true value
- \times $x \in \{0.0, 0.1, \dots, 9.9\}[g]$ measurement, observation

Decision strategy

- Decision strategy: a rule selecting a decision for any given value of the measured attribute(s).
- ▶ i.e. function $d = \delta(x)$.
- Example of husband's possible strategies:

- How many strategies?
- ▶ How to define which strategy is the best? How to sort them by quality?
- ▶ Define the risk of a strategy as a mean (expected) loss value

$$r(\delta) = \sum_{s} \sum_{s} \ell(s, \delta(s)) P(s, s)$$

Notes -

16 / 24

Overall, $3^4 = 81$ possible strategies (3 possible decisions for each of the 4 possible attribute values). There is some analogy of states and possible actions. Here, we reason about states - which are 3 (state of mind) - from features which are 4.

Any given value (of measured attribute) \dots Think about any possible state. Recall MDPs and RL.

- Reward (or penalty) was associated with state or state transition when executing an action R(s, a, s'). Similarly here, loss, $\ell(s, \delta(x))$, is associated with state and decision/action.
- Difference: policy / decision strategy.
 - MDP/RL: policy $\pi(s)$
 - Now: state s not directly observable anymore. Instead, policy / decision strategy, $\delta(x)$, needs to be defined over ther percepts/symptoms/attributes, x.
 - s and x need to be linked via P(x, s).

Decision strategy

- Decision strategy: a rule selecting a decision for any given value of the measured attribute(s).
- ▶ i.e. function $d = \delta(x)$.
- Example of husband's possible strategies:

` ,		x = irritated	x = upset	x = alarming
	nothing	nothing	pizza	g.T.c.
$\delta_2(x) =$	nothing	pizza	g.T.c.	g.T.c.
	g.T.c.	g.T.c.	g.T.c.	g.T.c.
$\delta_4(x) =$	nothing	nothing	nothing	nothing

- ► How many strategies?
- ▶ How to define which strategy is the best? How to sort them by quality?
- ▶ Define the risk of a strategy as a mean (expected) loss value

$$r(\delta) = \sum_{x} \sum_{s} \ell(s, \delta(x)) P(x, s)$$

Calculate $r(\delta_1)$ and $r(\delta_2)$, which strategy is better?

Bayes optimal strategy

► The Bayes optimal strategy : one minimizing mean risk.

$$\delta^* = \arg\min_{\delta} r(\delta)$$

From P(x,s) = P(s|x)P(x) (Bayes rule), we have

$$r(\delta) = \sum_{x} \sum_{s} \ell(s, \delta(x)) P(x, s) = \sum_{s} \sum_{x} \ell(s, \delta(x)) P(s|x) P(x)$$
$$= \sum_{x} P(x) \underbrace{\sum_{s} \ell(s, \delta(x)) P(s|x)}_{s}$$

▶ The optimal strategy is obtained by minimizing the conditional risk *separately* for each *x*:

$$\delta^*(x) = \arg\min_{d} \sum_{s} \ell(s, d) P(s|x)$$

18 / 24

Notes -

Optimal strategy: $\delta^*(x) = \arg\min_d \sum_s \ell(s, d) P(s|x)$

$\ell(s,d)$	d = nothing	d = pizza	d = g.T.c.
s = good	0	2	4
s = average	5	3	5
s = bad	10	9	6

P(x,s)	x = mild	x = irritated	x = upset	x = alarming
s = good	0.35	0.28	0.07	0.00
s = average	0.04	0.10	0.04	0.02
s = bad	0.00	0.02	0.05	0.03

$\delta(x)$	x = mild	x = irritated	x = upset	x = alarming
$\delta^*(x) =$??	??	??	??

Notes -

We need to recompute the table of joint probability P(s,x) into table of conditional probabilies P(s|x).

This can be done in two ways. A: Using product rule, P(s|x) = P(s,x)/P(x).

First to got P(x) we use Sum rule (marginalizing)		x = mild	x = irritated	x = upset	x = alarming
First, to get $P(x)$, we use Sum rule (marginalizing).	P(x)	0.39	0.40	0.16	0.05

Second, applying product rule, P(s|x) = P(s,x)/P(x).

B: calculating the probability on a "per column basis".

E. calculating the probability on a per column basis. E.g. for the first cell $\Lambda : 0.35/0.30 = 0.807 \text{ R} : 0.35/(0.35 \pm 0.04)$

E.g. for the first cell, A: $0.35/0.39 = 0.897$ B: $0.35/(0.35 + 0.04)$								
P(s x)	x = mild	x = irritated	x = upset	x = alarming				
s = good	0.897	0.7	0.438	0.00				
s = average	0.103	0.25	0.25	0.4				
s = bad	0.00	0.125	0.313	0.6				

Having the table of all P(s|x) we just mechanically insert into the equation in the slide title.

Statistical decision making: wrapping up

► Given:

- ightharpoonup A set of possible states : \mathcal{S}
- ightharpoonup A set of possible decisions : \mathcal{D}
- ▶ A loss function $I: \mathcal{D} \times \mathcal{S} \to \Re$
- ightharpoonup The range \mathcal{X} of the attribute
- ▶ Distribution $P(x, s), x \in \mathcal{X}, s \in \mathcal{S}$.

► Define:

- ► Strategy : function $\delta: \mathcal{X} \to \mathcal{D}$
- **Proof** Risk of strategy $\delta : r(\delta) = \sum_{x} \sum_{s} \ell(s, \delta(x)) P(x, s)$

▶ Bayes problem:

- ▶ Goal: find the optimal strategy $\delta^* = \arg \min_{\delta} r(\delta)$
- ► Solution: $\delta^*(x) = \arg\min_d \sum_s \ell(s, d) P(s|x)$ (for each x)

- ▶ Bayesian classification is a special case of statistical decision theory:
 - Attribute vector $\vec{x} = (x_1, x_2, ...)$: pixels 1, 2,
 - ▶ State set S = decision set $D = \{0, 1, \dots 9\}$.
 - ► State = actual class, Decision = recognized class
 - Loss function:

$$\ell(s,d) = \left\{ \begin{array}{ll} 0, & d = s \\ 1, & d \neq s \end{array} \right.$$

$$\delta^*(\vec{x}) = \arg\min_{d} \sum_{s} \underbrace{\ell(s, d)}_{0 \text{ if } d - s} P(s|\vec{x}) = \arg\min_{d} \sum_{s \neq d} P(s|\vec{x})$$

Obviously $\sum_{s} P(s|\vec{x}) = 1$, then:

$$P(d|\vec{x}) + \sum_{s \neq d} P(s|\vec{x}) = 1$$

Inserting into above:

$$\delta^*(\vec{x}) = \arg\min_{d} [1 - P(d|\vec{x})] = \arg\max_{d} P(d|\vec{x})$$

Notes -

- Classification as opposed to Decision
- Loss function simply counts errors (misclassifications)
- We consider all errors equally painful!
- More examples during the lab . . .
- The final result is not that surprising, is it? (Is it good or bad?)

- ▶ Bayesian classification is a special case of statistical decision theory:
 - Attribute vector $\vec{x} = (x_1, x_2, ...)$: pixels 1, 2,
 - ▶ State set S = decision set $D = \{0, 1, \dots 9\}$.
 - ► State = actual class, Decision = recognized class
 - Loss function:

$$\ell(s,d) = \left\{ \begin{array}{ll} 0, & d=s \\ 1, & d \neq s \end{array} \right.$$

$$\delta^*(\vec{x}) = \arg\min_{d} \sum_{s} \underbrace{\ell(s, d)}_{0 \text{ if } d=s} P(s|\vec{x}) = \arg\min_{d} \sum_{s \neq d} P(s|\vec{x})$$

Obviously $\sum_s P(s|\vec{x}) = 1$, then:

$$P(d|\vec{x}) + \sum_{s \neq d} P(s|\vec{x}) = 1$$

Inserting into above:

$$\delta^*(\vec{x}) = \arg\min_{d} [1 - P(d|\vec{x})] = \arg\max_{d} P(d|\vec{x})$$

Notes -

- Classification as opposed to Decision
- Loss function simply counts errors (misclassifications)
- We consider all errors equally painful!
- More examples during the lab . . .
- The final result is not that surprising, is it? (Is it good or bad?)
