# Outline

### C89 vs C99

C11

Jan Faigl, 2024

## Differences between C89 and C99

- Comments In C99 we can use a line comment that begins with //
- Identifiers C89 requires compilers to remember the first 31 characters vs. 63 characters in C99
  - Only the first 6 characters of names with external linkage are significant in C89 (no case sensitive)
  - In C99, it is the first 31 characters and case of letters matters
- Keywords 5 new keywords in C99: inline, restrict, \_Bool, \_Complex, and \_Imaginary
- Expressions
  - In C89, the results of / and % operators for a negative operand can be rounded either up or down. The sign of i % j for negative i or j depends on the implementation.
  - In C99, the result is always truncated toward zero and the sign of
    - i % j is the sign of *i*.

5 / 54

## Differences between C89 and C99

- Bool type C99 provides \_Bool type and macros in stdbool.h
- Loops C99 allows to declare control variable(s) in the first statement of the for loop
- Arrays C99 has
  - designated initializers and also allows
  - to use variable-length arrays
- Functions one of the directly visible changes is
  - In C89, declarations must precede statements within a block. In C99, it can be mixed.
- Preprocessor e.g.,
  - C99 allows macros with a variable number of arguments
  - C99 introduces \_\_func\_\_ macro which behaves as a string variable that stores the name of the currently executing function
- Input/Output conversion specification for the \*printf() and \*scanf() functions has been significantly changed in C99.

# Differences between C89 and C99 – Additional Libraries

- <stdbool.h> macros false and true that denote the logical values 0 and 1,
  respectively
- stdint.h> integer types with specified widths
- Inttypes.h> macros for input/output of types specified in <stdint.h>
- <complex.h> functions to perform mathematical operations on complex numbers
- <tgmath.h> type-generic macros for easier call of functions defined in <math.h>
  and <complex.h>
- <fenv.h> provides access to floating-point status flags and control modes

Further changes, e.g., see K. N. King: Appendix B

7 / 54

# Outline

### C89 vs C99

C11

Jan Faigl, 2024

# Overview of Changes in C11 - 1/2

- Memory Alignment Control \_Alignas, \_Alignof, and aligned\_alloc, <stdalign.h>
- Type-generic macros <u>Generic</u> keyword
- \_Noreturn keyword as the function specifier to declare function does not return by executing return statement (but, e.g., rather longjmp) <stdnoreturn.h>
- <threads.h> multithreading support
- <stdatomic.h> facilities for uninterruptible objects access
- Anonymous structs and unions, e.g., for nesting union as a member of a struct

9 / 54

# Overview of Changes in C11 - 2/2

- Unicode support <uchar.h>
- Bounds-checking functions e.g., strcat\_s() and strncpy\_s()
- gets() for reading a while line from the standard input has been removed.
  - It has been replaced by a safer version called gets\_s()
     In general, the bound-checking function aims to that the software written in C11 can be more robust against security loopholes and malware attacks.
- fopen() interface has been extended for exclusive create-and-open mode ("..x")
  that behaves as O\_CREAT|O\_EXCL in POSIX used for lock files
  - wx create file for writing with exclusive access
  - w+x create file for update with exclusive access
- Safer fopen\_s() function has been also introduced

10 / 54

### Generic Selection

 In C11, we can use a generic macros, i.e., macros with results that can be computed according to type of the pass variable (expression)

```
double f_i(int i)
                                              int main(void)
Ł
   return i + 1.0:
                                                 int i = 10:
                                                 double d = 10.0:
double f_d(double d)
                                                 printf("i = \%d; d = \%f n", i, d);
                                                 printf("Results of fce(i) %f\n", fce(i));
   return d - 1.0;
                                                 printf("Results of fce(d) %f\n", fce(d));
}
                                                 return EXIT_SUCCESS:
#define fce(X) Generic((X).\
int: f_i,∖
double: f d
                                                                     lec11/demo-matrix.cc
)(X)
 clang -std=c11 generic.c -o generic && ./generic
 i = 10: d = 10.000000
 Results of fce(i) 11.000000
 Results of fce(d) 9.000000
A function is selected according to the type of variable during compilation.
                                                   Static (parametric/compile-time) polymorphism
```

13 / 54

Jan Faigl, 2024

### С

- C was developed by Dennis Ritchie (1969–1973) at AT&T Bell Labs
- C is a procedural (aka structural) programming language
- C is a subset of C++
- The solution is achieved through a sequence of procedures or steps
- C is a function driven language

C++

- Developed by Bjarne Stroustrup in 1979 with C++'s predecessor "C with Classes"
- C++ is procedural but also an object oriented programming language
- C++ can run most of C code
- C++ can model the whole solution in terms of objects and that can make the solution better organized
- C++ is an object driven language

С

- Concept of virtual functions is not present in C
- No operator overloading
- Data can be easily accessed by other external functions
- C is a *middle level language*

- C++
- C++ offers the facility of using virtual functions
- C++ allows operator overloading
- Data can be put inside objects, which provides better data security
- C++ is a high level language
- C programs are divided into modules and C++ programs are divided into classes and procedures functions
- C programs use top-down approach

- - C++ programs use bottom-up approach

### С

- Does not provide namespaces
- Exception handling is not easy in C
- Inheritance is not possible
- Function overloading is not possible
- Functions are used for input/output, e.g., scanf() and printf()
- Does not support reference variables
- Does not support definition (overloading) operators

### C++

- Namespaces are available
- Exception handling through Try and Catch block
- Inheritance is possible
- Function overloading is possible (i.e., functions with the same name)
- Objects (streams) can be use for input/output, e.g., std::cin and std::cout
- Supports reference variables, using &
- C++ supports definition (overloading) of the operators

### Differences between C and C++

de-allocation

functions

**Classes and Objects** 

С

Provides malloc() (calloc()) for

It provides free() function for memory

Does not support for virtual and friend

dynamic memory allocation

Polymorphism is not possible

### C++

- C++ provides <u>new</u> operator for memory allocation
- It provides delete and (delete[]) operator for memory de-allocation
- C++ supports virtual and friend functions
- C++ offers polymorphism
- It supports both built-in and user-defined data types
- In C++ data and functions are easily mapped through objects
- C++ programs are saved in files with extension .cc, .cxx or .cpp

http://techwelkin.com/difference-between-c-and-c-plus-plus

and (dolo

• C programs are saved in files with extension .c

# Objects Oriented Programming (OOP)

# OOP is a way how to design a program to fulfill requirements and make the sources easy maintain.

- Abstraction concepts (templates) are organized into classes
  - Objects are instances of the classes
- Encapsulation
  - Object has its state hidden and provides interface to communicate with other objects by sending messages (function/method calls)
- Inheritance
  - Hierarchy (of concepts) with common (general) properties that are further specialized in the derived classes
- Polymorphism
  - An object with some interface could replace another object with the same interface

# Objects Oriented Programming (OOP)

OOP is a way how to design a program to fulfill requirements and make the sources easy maintain.

- Abstraction concepts (templates) are organized into classes
  - Objects are instances of the classes
- Encapsulation
  - Object has its state hidden and provides interface to communicate with other objects by sending messages (function/method calls)
- Inheritance
  - Hierarchy (of concepts) with common (general) properties that are further specialized in the derived classes
- Polymorphism
  - An object with some interface could replace another object with the same interface

# C++ for C Programmers

- C++ can be considered as an "extension" of C with additional concepts to create more complex programs in an easier way
- It supports to organize and structure complex programs to be better manageable with easier maintenance
- Encapsulation supports "locality" of the code, i.e., provide only public interfance and keep details "hidden"
  - Avoid unintentional wrong usage because of unknown side effects
  - Make the implementation of particular functionality compact and easier to maintain
  - Provide relatively complex functionality with simple to use interface
- Support a tighter link between data and functions operating with the data, i.e., classes combine data (properties) with functions (methods)

### From struct to class

- struct defines complex data types for which we can define particular functions, e.g., allocation(), deletion(), initialization(), sum(), print() etc.
- class defines the data and function working on the data including the initialization (constructor) and deletion (destructor) in a compact form
  - Instance of the class is an object, i.e., a variable of the class type

```
typedef struct matrix {
   int rows:
   int cols;
   double *mtx;
} matrix s:
```

```
matrix_s* allocate(int r, int c);
void release(matrix s **matrix):
void init(matrix_s *matrix);
void print(const matrix_s *matrix);
```

```
matrix_s *matrix = allocate(10, 10);
init(matrix);
print(matrix);
release(matrix):
```

```
class Matrix {
   const int ROWS:
   const int COLS:
   double *mtx;
   public:
   Matrix(int r, int c);
   ~Matrix(); //destructor
   void init(void);
   void print(void) const:
};
ł
   Matrix matrix(10, 10):
   matrix.init();
   matrix.print();
} // will call destructor
```

### Dynamic allocation

malloc() and free() and standard functions to allocate/release memory of the particular size in C

```
matrix_s *matrix = (matrix_s*)malloc(sizeof(matrix_s));
matrix->rows = matrix->cols = 0; //inner matrix is not allocated
print(matrix);
free(matrix):
```

C++ provides two keywords (operators) for creating and deleting objects (variables at the heap) new and delete

```
Matrix *matrix = new Matrix(10, 10); // constructor is called
matrix->print();
delete matrix;
```

new and delete is similar to malloc() and free(), but

- Variables are strictly typed and constructor is called to initialize the object
- For arrays, explicit calling of delete [] is required

#### Jan Faigl, 2024

## Dynamic allocation

malloc() and free() and standard functions to allocate/release memory of the particular size in C

```
matrix_s *matrix = (matrix_s*)malloc(sizeof(matrix_s));
matrix->rows = matrix->cols = 0; //inner matrix is not allocated
print(matrix);
free(matrix):
```

C++ provides two keywords (operators) for creating and deleting objects (variables at the heap) new and delete

```
Matrix *matrix = new Matrix(10, 10); // constructor is called
matrix->print();
delete matrix;
```

- new and delete is similar to malloc() and free(). but
  - Variables are strictly typed and constructor is called to initialize the object
  - For arrays, explicit calling of delete [] is required

```
int *array = new int[100]; // aka (int*)malloc(100 * sizeof(int))
delete[] array; // aka free(array)
```

Jan Faigl, 2024

# Reference

- In addition to variable and pointer to a variable, C++ supports references, i.e., a reference to an existing object
- Reference is an alias to existing variable, e.g.,

```
int a = 10:
int &r = a; // r is reference (alias) to a
r = 13; // a becomes 13
```

It allows to pass object (complex data structures) to functions (methods) without copying them Variables are passed by value int print(Matrix matrix) {// new local variable matrix is allocated // and content of the passed variable is copied ጉ int print(Matrix \*matrix) // pointer is passed ł matrix->print(); int print(Matrix &matrix) Ł // reference is passed - similar to passing pointer

**Classes and Objects**

Jan Faigl, 2024

## Class

Describes a set of objects - it is a model of the objects and defines:

Interface – parts that are accessible from outside

public, protected, private

- Body implementation of the interface (methods) that determine the ability of the objects of the class Instance vs class methods
- Data Fields attributes as basic and complex data types and structures (objects)
   Object composition
  - Instance variables define the state of the object of the <sup>}</sup>;
     particular class
  - Class variables common for all instances of the particular class

```
// header file - definition of the class
    type
class MyClass {
    public:
        /// public read only
        int getValue(void) const;
    private:
        /// hidden data field
        /// it is object variable
        int myData;
}
```

```
// source file - implementation of the
    methods
int MyClass::getValue(void) const
{
    return myData;
}
OOP in C++ (Part 1) 25 / 54
```

Jan Faigl, 2024

```
PRG - Lecture 11: OOP in C++ (Part 1)
```

# **Object Structure**

• The value of the object is structured, i.e., it consists of particular values of the object data fields which can be of different data type

Heterogeneous data structure unlike an array

- Object is an abstraction of the memory where particular values are stored
  - Data fields are called attributes or instance variables
- Data fields have their names and can be marked as hidden or accessible in the class definition

Following the encapsulation they are usually hidden

### **Object**:

- Instance of the class can be created as a variable declaration or by dynamic allocation using the new operator
- Access to the attributes or methods is using . or -> (for pointers to an object)

26 / 54

# **Object Structure**

• The value of the object is structured, i.e., it consists of particular values of the object data fields which can be of different data type

Heterogeneous data structure unlike an array

- Diject is an abstraction of the memory where particular values are stored
  - Data fields are called attributes or instance variables
- Data fields have their names and can be marked as hidden or accessible in the class definition

Following the encapsulation they are usually hidden

### **Object**:

- Instance of the class can be created as a variable declaration or by dynamic allocation using the new operator
- Access to the attributes or methods is using . or -> (for pointers to an object)

# Creating an Object – Class Constructor

- A class instance (object) is created by calling a constructor to initialize values of the instance variables
   Implicit/default one exists if not specified
- The name of the constructor is identical to the name of the class Class definition

Class implementation

```
MyClass::MyClass(int i) : _i(i)
class MyClass {
   public:
                                                ſ
      // constructor
                                                   _ii = i * i;
      MyClass(int i);
                                                   d = 0.0:
      MyClass(int i, double d);
                                                ጉ
                                                // overloading constructor
   private:
                                                MvClass::MvClass(int i, double d) : _i(i)
      const int i:
      int _ii:
                                                   _ii = i * i;
      double d:
                                                   _d = d:
};
                                                }
```

{

MyClass myObject(10); //create an object as an instance of MyClass
} // at the end of the block, the object is destroyed
MyClass \*myObject = new MyClass(20, 2.3); //dynamic object creation
delete myObject; //dynamic object has to be explicitly destroyed
Jan Faigl, 2024
PRG - Lecture 11: OOP in C++ (Part 1)

# Relationship between Objects

- Objects may contain other objects
- Object aggregation / composition
- Class definition can be based on an existing class definition so, there is a relationship between classes
  - Base class (super class) and the derived class
  - The relationship is transferred to the respective objects as instances of the classes

By that, we can cast objects of the derived class to class instances of ancestor

 Objects communicate between each other using methods (interface) that is accessible to them

## Access Modifiers

- Access modifiers allow to implement encapsulation (information hiding) by specifying which class members are private and which are public:
  - **public:** any class can refer to the field or call the method
  - protected: only the current class and subclasses (derived classes) of this class have access to the field or method
  - private: only the current class has the access to the field or method

Modifier	Class	Access Derived Class	"World"
public	✓.	<b>v</b>	$\checkmark$
protected	$\checkmark$	$\checkmark$	×
private	$\checkmark$	×	×

**Classes and Objects**

## Outline

Differences between C and C++

**Classes and Objects** 

**Classes and Objects** 

Constructor/Destructor

Example – Class Matrix

Jan Faigl, 2024

## Constructor and Destructor

- Constructor provides the way how to initialize the object, i.e., allocate resources
   Programming idiom Resource acquisition is initialization (RAII)
- Destructor is called at the end of the object life
  - It is responsible for a proper cleanup of the object
  - Releasing resources, e.g., freeing allocated memory, closing files
- Destructor is a method specified by a programmer similarly to a constructor However, unlike constructor, only single destructor can be specified
  - $\blacksquare$  The name of the destructor is the same as the name of the class but it starts with the character  $\sim$  as a prefix

# Constructor Overloading

- An example of constructor for creating an instance of the complex number
- In an object initialization, we may specify only real part or both the real and imaginary part

```
class Complex {
   public:
      Complex(double r)
          re = r:
       ን
      Complex(double r, double i)
      ſ
          re = r;
          im = i:
      ~Complex() { /* nothing to do in destructor */ }
   private:
      double re:
      double im;
};
                         Both constructors shared the duplicate code, which we like to avoid!
```

# Example – Constructor Calling 1/3

• We can create a dedicated initialization method that is called from different constructors

```
class Complex {
```

```
public:
   Complex(double r, double i) { init(r, i); }
   Complex(double r) { init(r, 0.0); }
   Complex() { init(0.0, 0.0); }
private:
   void init(double r, double i)
   {
      re = r;
      im = i;
   }
private:
   double re;
   double im:
```

};

#### Example – Constructor Calling 2/3

• Or we can utilize default values of the arguments that are combined with initializer list here

```
class Complex {
   public:
      Complex(double r = 0.0, double i = 0.0) : re(r), im(i) {}
   private:
      double re:
      double im:
};
int main(void)
Ł
   Complex c1;
   Complex c2(1.):
   Complex c3(1., -1.);
   return 0;
}
```

# Example – Constructor Calling 3/3

Alternatively, in C++11, we can use delegating constructor

```
class Complex {
   public:
      Complex(double r, double i)
      Ł
         re = r:
         im = i;
      }
      Complex(double r) : Complex(r, 0.0) {}
      Complex() : Complex(0.0, 0.0) \{\}
   private:
      double re:
      double im;
};
```

# Constructor Summary

- The name is identical to the class name
- The constructor does not have return value

Not even void

- Its execution can be prematurely terminated by calling return
- It can have parameters similarly as any other method (function)
- We can call other functions, but they should not rely on initialized object that is being done in the constructor
- Constructor is usually **public**
- **(private)** constructor can be used, e.g., for:
  - Classes with only class methods
  - Classes with only constants
  - The so called singletons

Prohibition to instantiate class

E.g., "object factorie

Jan Faigl, 2024

PRG - Lecture 11: OOP in C++ (Part 1)

# Class as an Extended Data Type with Encapsulation

Data hidding is utilized to encapsulate implementation of matrix

```
class Matrix {
    private:
        const int ROWS;
        const int COLS;
        double *vals;
};
```

1D array is utilized to have a continuous memory. 2D dynamic array can be used in C++11.

#### In the example, it is shown

- How initialize and free required memory in constructor and destructor
- How to report an error using exception and try-catch statement
- How to use references
- How to define a copy constructor
- How to define (overload) an operator for our class and objects
- How to use C function and header files in C++
- How to print to standard output and stream
- How to define stream operator for output
- How to define assignment operator

#### Example - Class Matrix - Constructor

- Class Matrix encapsulate dimension of the matrix
- Dimensions are fixed for the entire life of the object (const)

```
class Matrix {
                                           Matrix::Matrix(int rows, int cols) : ROWS(rows),
   public:
                                                 COLS(cols)
      Matrix(int rows, int cols);
                                           ſ
      ~Matrix();
                                              vals = new double[ROWS * COLS];
   private:
                                           }
      const int ROWS:
                                           Matrix::~Matrix()
      const int COLS;
      double *vals:
};
                                              delete[] vals;
                                           }
```

Notice, for simplicity we do not test validity of the matrix dimensions.

Constant data fields ROWS and COLS must be initialized in the constructor, i.e., in the initializer list

We should also preserve the order of the initialization as the variables are defined

Jan Faigl, 2024

PRG - Lecture 11: OOP in C++ (Part 1)

# Example - Class Matrix - Hidding Data Fields

- Primarily we aim to hide direct access to the particular data fields
- For the dimensions, we provide the so-called "accessor" methods
- The methods are declared as const to assure they are read only methods and do not modify the object (compiler checks that)
- Private method at () is utilized to have access to the particular cell at r row and c

column inline is used to instruct compiler to avoid function call and rather put the function body class Matrix { directly at the calling place. public:

```
inline int rows(void) const { return ROWS: } // const method cannot
inline int cols(void) const { return COLS: } // modify the object
```

```
private:
```

```
// returning reference to the variable allows to set the variable
// outside. it is like a pointer but automatically dereferenced
inline double& at(int r, int c) const
Ł
   return vals[COLS * r + c];
}
```

# Example – Class Matrix – Using Reference

- The at() method can be used to fill the matrix randomly
- The rand() function is defined in <stdlib.h>, but in C++ we prefer to include C libraries as <cstdlib> class Matrix { public: void fillRandom(void);

```
private:
      inline double& at(int r, int c) const { return vals[COLS * r + c]: }
};
```

```
#include <cstdlib>
```

```
void Matrix::fillRandom(void)
   for (int r = 0; r < ROWS; ++r) {
      for (int c = 0; c < COLS; ++c) {
         at(r, c) = (rand() % 100) / 10.0; // set vals[COLS * r + c]
      }
   }
}
```

In this case, it is more straightforward to just fill 1D array of vals for i in 0. (ROWS \* COLS).

# Example - Class Matrix - Getters/Setters

- Access to particular cell of the matrix is class Matrix { provided through the so-called *getter* and public: double getValueAt(int r, int c) const; *setter* methods void setValueAt(double v, int r, int c);
- The methods are based on the private at () }; method but will throw an exception if a cell out of ROWS and COLS would be requested

```
#include <stdexcept>
      double Matrix::getValueAt(int r, int c) const
      ſ
         if (r < 0 \text{ or } r \ge ROWS \text{ or } c < 0 \text{ or } c \ge COLS) 
            throw std::out_of_range("Out of range at Matrix::getValueAt");
         3
         return at(r, c);
      ን
      void Matrix::setValueAt(double v, int r, int c)
      ſ
         if (r < 0 \text{ or } r \ge ROWS \text{ or } c < 0 \text{ or } c \ge COLS) {
             throw std::out_of_range("Out of range at Matrix::setValueAt");
          ን
         at(r, c) = v;
      3
                                                          PRG – Lecture 11: OOP in C++ (Part 1)
Jan Faigl, 2024
```

# Example - Class Matrix - Exception Handling

- The code where an exception can be raised is put into the try-catch block
- The particular exception is specified in the catch by the class name
- We use the program standard output denoted as std::cout

```
We can avoid std:: by using namespace std;
      #include <iostream>
                                                                             Or just using std::cout;
      #include "matrix.h"
      int main(void)
         int ret = 0:
         trv {
            Matrix m1(3, 3):
            m1.setValueAt(10.5, 2, 3); // col 3 raises the exception
            m1.fillRandom();
         } catch (std::out_of_range& e) {
            std::cout << "ERROR: " << e.what() << std::endl;</pre>
            ret = -1
         3
         return ret:
      }
                                                                              lec11/demo-matrix.cc
                                                                                                    43 / 54
Jan Faigl, 2024
                                                 PRG – Lecture 11: OOP in C++ (Part 1)
```

#### Example – Class Matrix – Printing the Matrix

- We create a print () method to nicely print the matrix to the standard output
- Formatting is controlled by i/o stream manipulators defined in <iomanip> header file #include <iostream> #include <iomanip>

```
#include "matrix.h"
void print(const Matrix& m)
ſ
   std::cout << std::fixed << std::setprecision(1);</pre>
   for (int r = 0; r < m.rows(); ++r) {
      for (int c = 0; c < m.cols(); ++c) {</pre>
          std::cout << (c > 0 ? " " : "") << std::setw(4):</pre>
          std::cout << m.getValueAt(r, c);</pre>
      std::cout << std::endl;</pre>
   }
}
```

# Example - Class Matrix - Printing the Matrix

The matrix variable m1 is not copied as it is passed as reference to print() function #include <iostream> #include <iomanip> #include "matrix.h"

```
void print(const Matrix& m);
int main(void)
Ł
   int ret = 0:
   try {
      Matrix m1(3, 3);
      m1.fillRandom():
      std::cout << "Matrix m1" << std::endl:</pre>
      print(m1);
. . .
```

Example of the output

clang++ --pedantic matrix.cc demo-matrix.cc && ./a.out Matrix m1 1.3 9.7 9.8 1.5 1.2 4.3 87 08 98

lec11/matrix.h. lec11/matrix.cc. lec11/demo-matrix.cc

#### Example – Class Matrix – Copy Constructor

We may overload the constructor to create a copy of the object

```
class Matrix {
   public:
       . . .
       Matrix(const Matrix &m);
       . . .
};
```

We create an exact copy of the matrix

```
Matrix::Matrix(const Matrix &m) : ROWS(m.ROWS). COLS(m.COLS)
{ // copy constructor
   vals = new double[ROWS * COLS];
   for (int i = 0; i < ROWS * COLS; ++i) {</pre>
      vals[i] = m.vals[i];
   }
}
 Notice, access to private fields is allowed within in the class
```

We are implementing the class, and thus we are aware what are the internal data fields

# Example – Class Matrix – Dynamic Object Allocation

- We can create a new instance of the object by the <u>new</u> operator
- We may also combine dynamic allocation with the copy constructor
- Notice, the access to the methods of the object using the pointer to the object is by the -> operator

```
matrix m1(3, 3);
m1.fillRandom():
std::cout << "Matrix m1" << std::endl;</pre>
print(m1);
Matrix *m2 = new Matrix(m1):
Matrix *m3 = new Matrix(m2->rows(), m2->cols());
std::cout << std::endl << "Matrix m2" << std::endl:</pre>
print(*m2):
m3->fillRandom();
std::cout << std::endl << "Matrix m3" << std::endl:</pre>
print(*m3);
delete m2:
delete m3:
```

lec11/demo-matrix.cc

# Example - Class Matrix - Sum

The method to sum two matrices will return a new matrix

```
class Matrix {
   public:
      Matrix sum(const Matrix &m2):
```

```
}
```

```
• The variable ret is passed using the copy constructor
       Matrix Matrix::sum(const Matrix &m2)
       {
          if (ROWS != m2.ROWS or COLS != m2.COLS) {
             throw std::invalid_argument("Matrix dimensions do not match at Matrix::sum");
          }
          Matrix ret(ROWS, COLS);
          for (int i = 0; i < ROWS * COLS; ++i) {</pre>
             ret.vals[i] = vals[i] + m2.vals[i]:
          }
          return ret:
       }
                                                We may also implement sum as addition to the particular matrix
       The sum() method can be then used as any other method
       Matrix m1(3, 3);
       m1.fillRandom();
       Matrix *m2 = new Matrix(m1):
       Matrix m4 = m1.sum(*m2);
                                                   PRG – Lecture 11: OOP in C++ (Part 1)
Jan Faigl, 2024
```

### Example - Class Matrix - Operator +

- In C++, we can define our operators, e.g., + for sum of two matrices
- It will be called like the sum() method

```
class Matrix {
  public:
      Matrix sum(const Matrix &m2);
      Matrix operator+(const Matrix &m2);
}
```

In our case, we can use the already implemented sum() method

```
Matrix Matrix::operator+(const Matrix &m2)
ł
  return sum(m2);
}
```

The new operator can be applied for the operands of the Matrix type like as to default types Matrix m1(3,3): m1.fillRandom():

```
Matrix m2(m1), m3(m1 + m2); // use sum of m1 and m2 to init m3
print(m3);
```

#### Jan Faigl, 2024

#### PRG – Lecture 11: OOP in C++ (Part 1)

# Example – Class Matrix – Output Stream Operator

An output stream operator << can be defined to pass Matrix objects to the output stream</p> #include <ostream> class Matrix { ... }; std::ostream& operator<<(std::ostream& out, const Matrix& m);</pre>

It is defined outside the Matrix

```
#include <iomanip>
      std::ostream& operator<<(std::ostream& out, const Matrix& m)</pre>
      {
          if (out) {
              out << std::fixed << std::setprecision(1);</pre>
              for (int r = 0; r < m.rows(); ++r) {
                 for (int c = 0; c < m.cols(); ++c) {
                     out << (c > 0 ? " " : "") << std::setw(4):
                     out << m.getValueAt(r, c);</pre>
                 }
                 out << std::endl:
              }
          }
                                      "Outside" operator can be used in an output stream pipeline with other data types. In this case,
          return out:
                                      we can use just the public methods. But, if needed, we can declare the operator as a friend
      ን
                                      method to the class, which can access the private fields.
Jan Faigl, 2024
```

#### Example – Class Matrix – Example of Usage

```
Having the stream operator we can use + directly in the output
  std::cout << "\nMatrix demo using operators" << std::endl;</pre>
  Matrix m1(2, 2):
  Matrix m2(m1);
  m1.fillRandom();
  m2.fillRandom();
  std::cout << "Matrix m1" << std::endl << m1:</pre>
  std::cout << "\nMatrix m2" << std::endl << m2;</pre>
  std::cout << "\nMatrix m1 + m2" << std::endl << m1 + m2:
```

Example of the output operator Matrix demo using operators Matrix m1 Matrix m2 Matrix m1 + m21.2 5.4 0.8 3.1 0.4 2.3 2.2 4.6 3.3 7.2 5.5 11.8

lec11/demo-matrix.cc

# Example - Class Matrix - Assignment Operator =

```
class Matrix {
   public:
      Matrix& operator=(const Matrix &m)
      ł
         if (this != &m) { // to avoid overwriting itself
            if (ROWS != m.ROWS or COLS != m.COLS) {
               throw std::out_of_range("Cannot assign matrix with
                     different dimensions"):
            3
            for (int i = 0; i < ROWS * COLS: ++i) {</pre>
               vals[i] = m.vals[i]:
            }
         }
         return *this: // we return reference not a pointer
      }
};
// it can be then used as
Matrix m1(2,2), m2(2,2), m3(2,2);
m1.fillRandom();
m2.fillRandom():
m3 = m1 + m2:
std::cout << m1 << " + " << std::endl << m2 << " = " << std::endl << m3 << std::endl:
```

# Summary of the Lecture

Jan Faigl, 2024

PRG – Lecture 11: OOP in C++ (Part 1)

# **Topics Discussed**

- C89 vs C99 vs C11 a brief overview of the changes
- C vs C++ a brief overview of differences
- Object oriented programming in C++
  - Introduction to OOP
  - Classes and objects
  - Constructor
  - Examples of C++ constructs
    - Overloading constructors
    - References vs pointers
    - Data hidding getters/setters
    - Exception handling
    - Operator definition
    - Stream based output

Next: OOP - Polymorphism, inheritance, and virtual methods.
