PAL labs 8

9 / 11 / 2022

Let's have the alphabet $A = \{a, b, c, ..., z\}$. Let the symbol *a* be of order 1, *b* be of order 2, etc., up to *z* be of the order 26. We call a word over *A* ordered iff it holds that each symbol in the word is of smaller order than successors of that symbols in that world. Design an NFA which finds all ordered words in a text over the alphabet *A*.

Design an NFA over the alphabet $\{0,1,2\}$ which finds all occurrences of a string containing the same number of 0, 1 and 2 in a text.

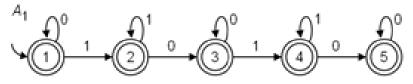

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Decide if these two regular expressions represent the same regular language.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- 1. $(01+0)^*0$
- 2. $0(10+0)^*$

Informally describe a which language is accepted by the automaton over the alphabet $\{0,1\}$. Write down a regular expression describing that language.

(日)

ж

Write down a regular expression describing the maximal (w.r.t. inclusion) set M of strings over the alphabet $\{a, b, c\}$ such that:

1. each string in M starts and ends with the symbol b,

2. each string in M contains exactly one symbol c,

3. each string in M cannot contain the symbol a on odd position (positions are numbered from 1)

Automaton A_1 accepts language L_1 , automaton A_2 accepts language L_2 . Both automatons have *n* states. The alphabet is the same for both automatons and contains *k* letters. What is the asymptotic complexity of an algorithm which decide if the language $L_1 \cap L_2$ is finite?

In a text over the alphabet $\{a, b, c, d\}$, we are asked to find all occurrences of all substrings which begin and end with b, and they have Hamming distance greater than 2 from the pattern *abbbcdabbcdab*. Design a non-deterministic automaton to solve the task.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Design an automaton which finds all occurrences of words which have Levenshtein distance up to k from a pattern, using epsilon transition, in a text, for pattern of length 6 and k = 3. How will an equivalent automaton look after removing epsilon transition?
