# Classical Planning

**Definition.** A *planning task* is a 4-tuple  $\Pi = (V, A, I, G)$  where:

- $V$  is a set of *state variables*, each  $v \in V$  with a finite *domain*  $D_v$ .
- $A$  is a set of *actions*; each  $a \in A$  is a triple  $(pre_a, eff_a, c_a)$ , of *precondition* and *effect* (partial assignments), and the action's *cost*  $c_a \in \mathbb{R}^{0+}$ .
- *Initial state*  $I$  (complete assignment), *goal*  $G$  (partial assignment).

# Classical Planning

**Definition.** A *planning task* is a 4-tuple  $\Pi = (V, A, I, G)$  where:

- $V$  is a set of *state variables*, each  $v \in V$  with a finite *domain*  $D_v$ .
- $A$  is a set of *actions*; each  $a \in A$  is a triple  $(pre_a, eff_a, c_a)$ , of *precondition* and *effect* (partial assignments), and the action's *cost*  $c_a \in \mathbb{R}^{0+}$ .
- *Initial state*  $I$  (complete assignment), *goal*  $G$  (partial assignment).

**Running Example:**

- $V = \{t, p_1, p_2, p_3, p_4\}$   
with  $D_t = \{l_1, l_2, l_3\}$  and  $D_{p_i} = \{t, l_1, l_2, l_3\}$ .
- $A = \{load(p_i, x), unload(p_i, x), drive(x, x')\}$

# Semantics – The State Space of a Planning Task

**Definition.** Let  $\Pi = (V, A, I, G)$  be an FDR planning task. The *state space* of  $\Pi$  is the labeled transition system  $\Theta_{\Pi} = (S, L, c, T, I, S^G)$  where:

- The *states*  $S$  are the complete variable assignments.
- The *labels*  $L = A$  are  $\Pi$ 's actions; the *cost function*  $c$  is that of  $\Pi$ .
- The *transitions* are  $T = \{s \xrightarrow{a} s' \mid pre_a \subseteq s, s' = s[[a]]\}$ .  
 If  $pre_a \subseteq s$ , then  $a$  is *applicable* in  $s$  and, for all  $v \in V$ ,  $s[[a]][v] := eff_a[v]$  if  $eff_a[v]$  is defined and  $s[[a]][v] := s[v]$  otherwise.  
 If  $pre_a \not\subseteq s$ , then  $s[[a]]$  is undefined.
- The *initial state*  $I$  is identical to that of  $\Pi$ .
- The *goal states*  $S^G = \{s \in S \mid G \subseteq s\}$  are those that satisfy  $\Pi$ 's goal.

# Semantics – The State Space of a Planning Task

**Definition.** Let  $\Pi = (V, A, I, G)$  be an FDR planning task. The *state space* of  $\Pi$  is the labeled transition system  $\Theta_{\Pi} = (S, L, c, T, I, S^G)$  where:

- The *states*  $S$  are the complete variable assignments.
- The *labels*  $L = A$  are  $\Pi$ 's actions; the *cost function*  $c$  is that of  $\Pi$ .
- The *transitions* are  $T = \{s \xrightarrow{a} s' \mid pre_a \subseteq s, s' = s[a]\}$ .  
 If  $pre_a \subseteq s$ , then  $a$  is *applicable* in  $s$  and, for all  $v \in V$ ,  $s[a][v] := eff_a[v]$  if  $eff_a[v]$  is defined and  $s[a][v] := s[v]$  otherwise.  
 If  $pre_a \not\subseteq s$ , then  $s[a]$  is undefined.
- The *initial state*  $I$  is identical to that of  $\Pi$ .
- The *goal states*  $S^G = \{s \in S \mid G \subseteq s\}$  are those that satisfy  $\Pi$ 's goal.

→ **Solution (“Plan”)**: Action sequence mapping  $I$  into  $s \in S^G$ .

Optimal plan: Minimum summed-up cost.

# A successful approach: Heuristic Search

init

4.  $\varphi \wedge \psi$  (“Conjunction”)
5.  $\varphi \vee \psi$  (“Disjunction”)
6.  $\varphi \rightarrow \psi$  (“Implication”)
7.  $\varphi \leftrightarrow \psi$  (“Equivalence”)

# States as Logical Formulas

- Propositions (atoms in STRIPS):  $\langle v, d \rangle$  Does var  $v$  have value  $d$ ?
- How to represent a state as a logical formula?

# States as Logical Formulas

- Propositions (atoms in STRIPS):  $\langle v, d \rangle$  Does var  $v$  have value  $d$ ?
- How to represent a state as a logical formula?

$l_1$  ———  $l_2$  ———  $l_3$      $\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_1 \rangle$

**Disclaimer:** In propositional logic there is no closed-world assumption. In our examples, we ignore state invariants:  $\langle t, l_1 \rangle \leftrightarrow (\neg \langle t, l_2 \rangle \wedge \neg \langle t, l_3 \rangle)$ .

Otherwise the state above would be written as:

$$\langle t, l_1 \rangle \wedge \neg \langle t, l_2 \rangle \wedge \neg \langle t, l_3 \rangle \wedge \langle p_1, l_1 \rangle \wedge \neg \langle p_1, l_2 \rangle \wedge \neg \langle p_1, l_3 \rangle \wedge \langle p_2, l_1 \rangle \wedge \neg \langle p_2, l_2 \rangle \wedge \neg \langle p_2, l_3 \rangle$$

# Sets of States as Logical Formulas

 $l_1 \text{ — } l_2 \text{ — } l_3$ 

 $\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_1 \rangle$

# Sets of States as Logical Formulas

 $l_1 \text{ ————— } l_2 \text{ ————— } l_3$ 

 $\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_1 \rangle$ 

 $l_1 \text{ ————— } l_2 \text{ ————— } l_3$ 

 $\langle t, l_1 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_1 \rangle$ 

 $l_1 \text{ ————— } l_2 \text{ ————— } l_3$ 

 $\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_2 \rangle$ 

 $l_1 \text{ ————— } l_2 \text{ ————— } l_3$ 

 $\langle t, l_1 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_2 \rangle$

# Sets of States as Logical Formulas

$$\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_1 \rangle$$

$$\vee$$

$$\langle t, l_1 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_1 \rangle$$

# Operations on Set of States: Search

So, what is missing for doing search via operations on logical formulas?

# Operations on Set of States: Search

So, what is missing for doing search via operations on logical formulas?

→ **Successor generation**: given the set of states with  $g = i$ , what is the set of states with  $g = (i + 1)$ ?

# Operations on Set of States: Search

So, what is missing for doing search via operations on logical formulas?

→ **Successor generation**: given the set of states with  $g = i$ , what is the set of states with  $g = (i + 1)$ ? **depends on the set of actions!**

# Planning Actions as Logical Formulas

Action  $a = \langle pre(a), eff(a) \rangle$

- Precondition: An action is only applicable in a state if  $s \models pre(a)$
- Effect: changes the value of each variable  $v$  to  $eff(a)[v]$  if  $eff(a)[v]$  is specified

Transition Relation: represents an action  $a$  as the relation (set of pairs of states) containing  $(s, s')$  where  $a$  is applicable in  $s$  resulting in  $s'$ .

- We need to double all propositions: for  $s$  and  $s'$
- The transition relation is

$$pre(a) \wedge eff'(a) \wedge \bigwedge_{v(x) \notin eff(a)} (x \leftrightarrow x')$$

# Planning Actions as Logical Formulas

Transition Relation: represents an action  $a$  as the relation (set of pairs of states) containing  $(s, s')$  where  $a$  is applicable in  $s$  resulting in  $s'$ .

# Computing the Predecessors (Pre-Image Computation)

Pre-image: Given a set of states  $S(x)$  and a TR  $T(x, x')$  generate the predecessor states

$$\text{pre-image}(S(x), T(x, x')) = \exists x' . S(x)[x' \leftrightarrow x] \wedge T(x, x')$$

- Corresponds to regression [Rin08]

# Agenda

- ① Classical Planning: Models, Approaches
- ② Symbolic Representation of Planning Tasks
- ③ Binary Decision Diagrams**
- ④ Symbolic Search
- ⑤ Heuristic Search
- ⑥ Symbolic Abstraction Heuristics
- ⑦ Conclusion

# How to Represent Logical Formulas in Practice?

- To take advantage of the symbolic representations of sets of states, one needs an efficient representation
- The same set of states can be represented by very different formulas, e.g., the set of all states can be represented by  $\top$  or by:

$$\begin{aligned} & (\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_1 \rangle) \vee (\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_2 \rangle) \vee (\langle t, l_1 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, t \rangle) \vee \\ & (\langle t, l_1 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_1 \rangle) \vee (\langle t, l_1 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_2 \rangle) \vee (\langle t, l_1 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, t \rangle) \vee \\ & (\langle t, l_1 \rangle \wedge \langle p_1, t \rangle \wedge \langle p_2, l_1 \rangle) \vee (\langle t, l_1 \rangle \wedge \langle p_1, t \rangle \wedge \langle p_2, l_2 \rangle) \vee (\langle t, l_1 \rangle \wedge \langle p_1, t \rangle \wedge \langle p_2, t \rangle) \vee \\ & (\langle t, l_2 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_1 \rangle) \vee (\langle t, l_2 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, l_2 \rangle) \vee (\langle t, l_2 \rangle \wedge \langle p_1, l_1 \rangle \wedge \langle p_2, t \rangle) \vee \\ & (\langle t, l_2 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_1 \rangle) \vee (\langle t, l_2 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, l_2 \rangle) \vee (\langle t, l_2 \rangle \wedge \langle p_1, l_2 \rangle \wedge \langle p_2, t \rangle) \vee \\ & (\langle t, l_2 \rangle \wedge \langle p_1, t \rangle \wedge \langle p_2, l_1 \rangle) \vee (\langle t, l_2 \rangle \wedge \langle p_1, t \rangle \wedge \langle p_2, l_2 \rangle) \vee (\langle t, l_2 \rangle \wedge \langle p_1, t \rangle \wedge \langle p_2, t \rangle) \vee \end{aligned}$$

→How to choose the “best” representation? →As usual, it involves a trade-off between memory and time efficiency

\*: In SDDs,  $\vee$  and  $\wedge$  with compression is not polynomial.

**P**: polynomial in **the size of the representation**

# Binary Decision Diagrams (BDDs)

A function can be represented by a decision tree (e.g.  $x_2 \rightarrow x_3$ )

→ Each node decomposes the formula according to one variable:

$$\psi = (x_i \wedge \varphi) \vee (\neg x_i \wedge \varphi')$$

# Binary Decision Diagrams (BDDs)

A function can be represented by a decision tree (e.g.  $x_2 \rightarrow x_3$ )

→ Each node decomposes the formula according to one variable:

$$\psi = (x_i \wedge \varphi) \vee (\neg x_i \wedge \varphi')$$

- 1 Assume fixed variable ordering

# Binary Decision Diagrams (BDDs)

A function can be represented by a decision tree (e.g.  $x_2 \rightarrow x_3$ )

→ Each node decomposes the formula according to one variable:

$$\psi = (x_i \wedge \varphi) \vee (\neg x_i \wedge \varphi')$$

- ① Assume fixed variable ordering
- ② Represent each node only once (each  $\psi$  has a single node)

# Binary Decision Diagrams (BDDs)

- $Count(n_3) = 2$
- $Count(n_2) = Count(n_3) + 2^2 = 6$
- $Count(n_1) = 2 \cdot Count(n_2) + 2^2 Count(n_3) = 20$
- Total:

# How to Count

## Question!

How many states are in the following BDD?

$x_1$

$x_2$

$x_3$

$x_4$

$x_5$

$x_6$

- Each node corresponds to a set of state suffixes, e.g.,  $n_3 = \{(x_5, \bar{x}_6), (x_5, x_6)\}$

- $Count(n_3) = 2$

- $Count(n_2) = Count(n_3) + 2^2 = 6$

- $Count(n_1) = 2 \cdot Count(n_2) + 2^2 Count(n_3) = 20$

- Total: 40

→ Each node needs to be processed only once

# BDD Operations: And

- Recursive function over two BDDs  $f$  and  $g$
- Base case(s):  $f$  (or  $g$ ) is a constant:
  - $(f = \top) \implies f \wedge g = g$
  - $(f = \perp) \implies f \wedge g = \perp$
- Recursive case ( $v = \text{var}(f) = \text{var}(g)$ )

$$f = (v \wedge f_1) \vee (\neg v \wedge f_2), \quad g = (v \wedge g_1) \vee (\neg v \wedge g_2)$$

$$f \wedge g = (f_1 \wedge g_1, f_2 \wedge g_2)$$

- Recursive case ( $\text{var}(f) < \text{var}(g)$ )

$$f \wedge g = (f_1 \wedge g, f_2 \wedge g)$$

→ Ensure that nodes are not duplicated

# BDD Operations: And

→Complexity?

# BDD Operations: And

→Complexity? Quadratic,  $O(|f||g|)$

# BDD Operations: And

→Complexity? Quadratic,  $O(|f||g|)$

→Important to keep a cache  $(n_i, n_j) \rightarrow n_k$  to avoid duplicate work

# BDD Variable Ordering

$$(x_1 \neq y_1) \vee (x_2 \neq y_2) \vee (x_3 \neq y_3)$$

Exponential ( $> 2^{n+1}$ )

Polynomial ( $3n + 2$ )

# Practical Strategies for a Good Variable Ordering

**Static Variable Ordering:** Put causally-related variables close [KE11]

Choose ordering  $o$  that minimizes  $\sum_{v_i, v_j \in CG} d_o(v_i, v_j)^2$

→No strong theoretical guarantees [KH13] but compares well against other alternatives [BRKM91, CHP93, Mai09, MWBSV88, MIY90]

# Practical Strategies for a Good Variable Ordering

**Static Variable Ordering:** Put causally-related variables close [KE11]

Choose ordering  $o$  that minimizes 
$$\sum_{v_i, v_j \in CG} d_o(v_i, v_j)^2$$

→No strong theoretical guarantees [KH13] but compares well against other alternatives [BRKM91, CHP93, Mai09, MWBSV88, MIY90]

**Dynamic Variable Ordering:** variable re-ordering to minimize the size of the BDDs generated so far

- Finding the optimal BDD ordering is NP-hard [Bry86]
- But practical approximations (based on local-search) exist [Rud93].
- Applied in planning with good results by dynamic-Gamer [KH14]

# Complexity Results

Exponential	Connect-4 Tic-tac-toe Gomoku	

Can variable orderings schemas based on the causal graph give us theoretical guarantees for the size of BDDs in the search? [KH14]

→ Mostly not.

# Efficient Image Computation: Variable Ordering

Variable Ordering: Interleave variables  $x$  and  $x'$

→ The TR of an action has linear size on the number of variables

# Efficient Image Computation

## Transition Relation Partitioning [BCL91, JVB08]

Given a set of  $K$  actions **with the same cost**, replace  $T_i(x, x')$  and  $T_j(x, x')$  by  $T_i(x, x') \vee T_j(x, x')$

# Efficient Image Computation

## Transition Relation Partitioning [BCL91, JVB08]

Given a set of  $K$  actions **with the same cost**, replace  $T_i(x, x')$  and  $T_j(x, x')$  by  $T_i(x, x') \vee T_j(x, x')$

# Efficient Image Computation

## Transition Relation Partitioning [BCL91, JVB08]

Given a set of  $K$  actions **with the same cost**, replace  $T_i(x, x')$  and  $T_j(x, x')$  by  $T_i(x, x') \vee T_j(x, x')$

→ Merge as many TRs as possible given the available memory [TEK13, TAKE17]

# Uses of Decision Diagrams

In classical planning:

- Symbolic search (this lecture)
- Representation of state-dependent action costs [GKM15]
- Subsumption of partial states [AFB14]
- Dominance pruning [TH15]

Also very important in other areas:

- Model checking
- Hardware design and verification

# BDD Packages

Library	Language	Reference
CUDD	C/C++	[Som]
CacBDD	C++	[LSX13]
BuDDy	C	[CWWG]
CAL	C	
Sylvan	C	[vDvdP15]
JDD	Java	[Vah]
BeeDeeDee	Java	[LMS14]

→ Not clear best performer. CUDD, BuDDy, CacBDD have good results in symbolic model-checking [vDHJ<sup>+</sup>15].

→ There are interfaces that adapt these libraries for other languages like Java, Python, Haskell, ...

# Agenda

- 1 Classical Planning: Models, Approaches
- 2 Symbolic Representation of Planning Tasks
- 3 Binary Decision Diagrams
- 4 Symbolic Search**
- 5 Heuristic Search
- 6 Symbolic Abstraction Heuristics
- 7 Conclusion

# How to do Search

We have all the necessary ingredients to do search:

- Representation of the initial state and goal
- Operation to generate successors: image operation
- Operation to check if goal has been reached:  $S \wedge G \neq \emptyset$

# How to do Search

We have all the necessary ingredients to do search:

- Representation of the initial state and goal
- Operation to generate successors: image operation
- Operation to check if goal has been reached:  $S \wedge G \neq \emptyset$

→ We can devise versions of the standard search algorithms that take advantage of the symbolic representation to compute the successors from a set of states at the same time

# Symbolic Breadth-First Search

**Input:** Planning Task  $\Pi = (V, A, I, G)$

$S_0 \leftarrow I ;$

$C \leftarrow \emptyset ;$

$i \leftarrow 0 ;$

**while**  $S_i \neq \emptyset$  **do**

**if**  $S_i \wedge G$  **then**

**return** Plan ;

**end**

$C \leftarrow C \vee S_i ;$

$S_{i+1} \leftarrow \text{image}(S_i, TR) \wedge \neg C ;$

$i \leftarrow i + 1 ;$

**end**

**return** Unsolvable ;

# Symbolic Breadth-First Search

# Symbolic Uniform-Cost Search

Expand set of states  $S_i$  with minimum  $g$ -value  $i$

- Zero-cost breadth-first search to obtain all states reachable with  $g = i$
- For each TR with action cost  $c$ :
  - Use image to compute states reachable with  $i + c$
  - Insert the result in the corresponding bucket (disjunction)

# Symbolic Uniform-Cost Search

Expand set of states  $S_i$  with minimum  $g$ -value  $i$

- Zero-cost breadth-first search to obtain all states reachable with  $g = i$
- For each TR with action cost  $c$ :
  - Use image to compute states reachable with  $i + c$
  - Insert the result in the corresponding bucket (disjunction)

# Symbolic Backward Uniform-Cost Search

We can perform the search in backward direction:

- Start with the set of goal states
- Use pre-image instead of image operation

Challenges:

- ① Multiple goal states
- ② Subsumption of partial states
- ③ Spurious states

# Symbolic Backward Uniform-Cost Search

We can perform the search in backward direction:

- Start with the set of goal states
- Use pre-image instead of image operation

Challenges:

- ① Multiple goal states → Not a problem in symbolic search!
- ② Subsumption of partial states → Not a problem in symbolic search!
- ③ Spurious states

# Symbolic Backward Uniform-Cost Search

We can perform the search in backward direction:

- Start with the set of goal states
- Use pre-image instead of image operation

Challenges:

- ① Multiple goal states → Not a problem in symbolic search!
- ② Subsumption of partial states → Not a problem in symbolic search!
- ③ Spurious states → Solution: state-invariant pruning [TAKE17]
  - Compute state invariants, e.g.,  $h^2$  mutexes
  - Encode the set of spurious states as a BDD
  - Remove spurious states from the goal and the TRs

# Symbolic Bidirectional Uniform-Cost Search

- Do forward and backward search at the same time
- Decide forward or backward direction at each step

$$g_f = 0$$

$$g_b = 0$$

# Symbolic Bidirectional Uniform-Cost Search

- Do forward and backward search at the same time
- Decide forward or backward direction at each step

$$g_f = 0$$

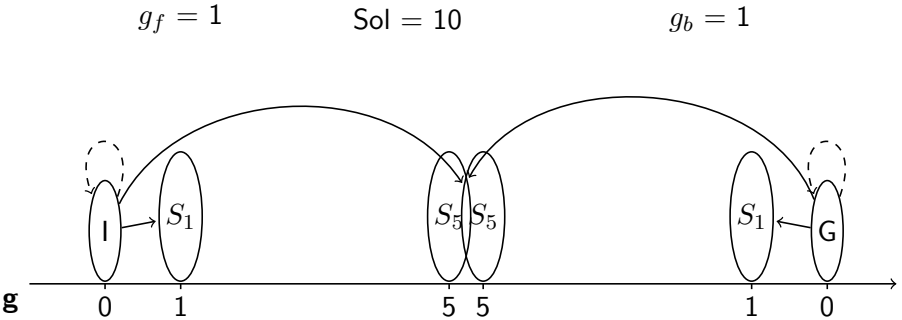

$$g_b = 0$$

# Symbolic Bidirectional Uniform-Cost Search

- Do forward and backward search at the same time
- Decide forward or backward direction at each step
- Stop when  $g_f + g_b + \min_{a \in AC}(a) \geq Sol$

# Symbolic Bidirectional Uniform-Cost Search

- Do forward and backward search at the same time
- Decide forward or backward direction at each step
- Stop when  $g_f + g_b + \min_{a \in AC}(a) \geq Sol$

- 2 Symbolic Representation of Planning Tasks
- 3 Binary Decision Diagrams
- 4 Symbolic Search
- 5 Heuristic Search
- 6 Symbolic Abstraction Heuristics**
- 7 Conclusion

# Abstractions

**Abstraction:** function  $\alpha : S \mapsto S^\alpha$ . Induces an **abstract state space** s.t.:

- ⓪  $I^\alpha = \alpha(I)$ .
- ⓪  $S^{\alpha G} = \{\alpha(s) \mid s \in S^G\}$ . /\* preserve goal states \*/
- ⓪  $T^\alpha = \{(\alpha(s), l, \alpha(t)) \mid (s, l, t) \in T\}$ . /\* preserve transitions \*/

# Abstractions

**Abstraction:** function  $\alpha : S \mapsto S^\alpha$ . Induces an **abstract state space** s.t.:

- (i)  $I^\alpha = \alpha(I)$ .
- (ii)  $S^{\alpha G} = \{\alpha(s) \mid s \in S^G\}$ . /\* preserve goal states \*/
- (iii)  $T^\alpha = \{(\alpha(s), l, \alpha(t)) \mid (s, l, t) \in T\}$ . /\* preserve transitions \*/

# Pattern Databases [CS98, Ede01, HBH<sup>+</sup>07]

**Pattern Databases:** Select a subset of variables  $V^\alpha \subseteq V$  (pattern).  
The mapping  $\alpha$  is defined as the projection onto  $V^\alpha$ .

# Abstraction Heuristics

Use the **optimal goal-distance in the abstract state space** as an (admissible) estimate for the distance in the concrete state space:

$$h(s) = h^*(\alpha(s))$$

# Abstraction Heuristics

Use the **optimal goal-distance in the abstract state space** as an (admissible) estimate for the distance in the concrete state space:

$$h(s) = h^*(\alpha(s))$$

- 1 Precompute  $h^*$  for all  $\alpha(s) \in S^\alpha$  by performing a **backward uniform-cost search** in the abstract state space
- 2 Store them in a **look-up table**

# Abstraction Heuristics

Use the **optimal goal-distance in the abstract state space** as an (admissible) estimate for the distance in the concrete state space:

$$h(s) = h^*(\alpha(s))$$

- 1 Precompute  $h^*$  for all  $\alpha(s) \in S^\alpha$  by performing a **backward uniform-cost search** in the abstract state space
  - Searching the entire abstract state space? That's what **symbolic search** is good for!
- 2 Store them in a **look-up table**

# Symbolic Pattern Databases

Do symbolic backward uniform-cost search with only a subset of variables

- Do not have a limit on the number of variables to consider
- Truncate the search if it takes too much time or memory [AHS07]
- Using all variables: Symbolic Perimeter

# Symbolic Pattern Databases

Do symbolic backward uniform-cost search with only a subset of variables

- Do not have a limit on the number of variables to consider
- Truncate the search if it takes too much time or memory [AHS07]
- Using all variables: Symbolic Perimeter

→ Really strong for heuristic search planners too [FTLB17]!

# Agenda

- 2 Symbolic Representation of Planning Tasks
- 3 Binary Decision Diagrams
- 4 Symbolic Search
- 5 Heuristic Search
- 6 Symbolic Abstraction Heuristics
- 7 Conclusion

# Summary

- Symbolic search represents sets of states as Binary Decision Diagrams (BDDs) to perform search efficiently:
  - Implicitly exploits structure of the problem
  - Very useful for regression
- Symbolic bidirectional uniform-cost search has very good performance without using any heuristic
  - Backward search can be understood as a (perimeter) heuristic
- Heuristics can also be used in symbolic search (though is slightly harder and not as useful as in explicit-state search)
