Problem Statement

Integer Linear Programming (ILP)

The ILP problem is given by matrix $\mathbf{A} \in \mathbb{R}^{m \times n}$ and vectors $\mathbf{b} \in \mathbb{R}^m$ and $\mathbf{c} \in \mathbb{R}^n$. The goal is to find a vector $\mathbf{x} \in \mathbb{Z}^n$ such that $\mathbf{A} \cdot \mathbf{x} \leq \mathbf{b}$ and $\mathbf{c}^T \cdot \mathbf{x}$ is the maximum.

Usually, the problem is given as $\max \{c^T \cdot x : \mathbf{A} \cdot x \leq b, x \in \mathbb{Z}^n\}$.

• A large number of practical optimization problems can be modeled and solved using Integer Linear Programming - ILP.

Comparison of ILP and LP

- The ILP problem differs from the LP problem in allowing only integer-valued variables. If some variables can contain real numbers, the problem is called Mixed Integer Programming - MIP. Often MIP is also called ILP, and we will use the term ILP when at least one variable has integer domain.
- If we solve the ILP problem by an LP algorithm and then just round the solution, we could not only get the suboptimal solution, we can also obtain a solution which is not feasible.
- While the LP is solvable in polynomial time, ILP is NP-hard, i.e. there is no known algorithm which can solve it in polynomial time.
- Since the ILP solution space is not a convex set, we cannot use convex optimization techniques.

Example ILP1a: 2-Partition Problem

2-Partition Problem

- Instance: Number of banknotes $n \in \mathbb{Z}^+$ and their values p_1, \dots, p_n , where $p_{i \in 1...n} \in \mathbb{Z}^+$.
- **Decision:** Is there a subset $S \subseteq \{1, ..., n\}$ such that $\sum_{i \in S} p_i = \sum_{i \notin S} p_i$?

The decision problem, which can be written while using the equation above as an ILP constraint (but we write it differently).

•
$$x_i = 1$$
 iff $i \in S$

This is one of the "easiest" NP-complete problems.

min 0 subject to:
$$\sum_{i \in 1...n} x_i * p_i = 0.5 * \sum_{i \in 1...n} p_i$$
 parameters: $n \in \mathbb{Z}^+, p_{i \in 1...n} \in \mathbb{Z}^+$ variables: $\mathbf{x_{i \in 1...n}} \in \{\mathbf{0},\mathbf{1}\}$

Example ILP1b: Fractional Variant of the 2-Part. Prob.

We allow division of banknotes such that $x_{i \in 1..n} \in \langle 0, 1 \rangle$. The solution space is a convex set - the problem can be formulated by LP:

min 0 subject to:
$$\sum_{i \in 1...n} x_i * p_i = 0.5 * \sum_{i \in 1...n} p_i$$

$$\mathbf{x_i} \leq \mathbf{1} \quad i \in 1...n$$
 parameters: $n \in \mathbb{Z}_0^+, \ p_{i \in 1...n} \in \mathbb{Z}_0^+$ variables:
$$\mathbf{x_{i \in 1..n}} \in \mathbb{R}_0^+$$

- For example: p = [100, 50, 50, 50, 20, 20, 10, 10] the fractional variant allows for x = [0, 0, 0.9, 1, 1, 1, 1, 1] and thus divides the banknotes into equal halves 100 + 50 + 5 = 45 + 50 + 20 + 20 + 10 + 10, but this instance does not have a non-fractional solution.
- For some non-fractional instances we can easily find that they cannot be partitioned (e.g. when the sum of all values divided by the greatest common divisor is not an even number), however we do not know any alg that can do it in polynomial time for any non-fractional instance.

Example ILP1c: 2-Partition Prob. - Optimization Version

- The decision problem can be solved by an optimization algorithm while using a **threshold** value (here $0.5 * \sum_{i \in 1...n} p_i$) and comparing the optimal solution with the threshold.
- Moreover, when the decision problem has no solution, the optimization algorithm returns a value that is closest to the threshold.

$$\begin{array}{ll} \text{min} & C_{max} \\ \text{subject to:} & \sum_{i \in 1...n} x_i * p_i \leq C_{max} \\ & \sum_{i \in 1...n} (1-x_i) * p_i \leq C_{max} \\ \text{parameters:} & n \in \mathbb{Z}_0^+, \ p_{i \in 1...n} \in \mathbb{Z}_0^+ \\ \text{variables:} & x_{i \in 1..n} \in \{0,1\}, \ C_{max} \in \mathbb{R}_0^+ \end{array}$$

Application: the scheduling of nonpreemptive tasks $\{T_1, T_2, ..., T_n\}$ with processing times $[p_1, p_2, ..., p_n]$ on two parallel identical processors and minimization of the completion time of the last task (i.e. maximum completion time C_{max}) - $P2 \mid\mid C_{max}$. The fractional variant of 2-partition problem corresponds to the preemptive scheduling problem.

Example ILP2a: Shortest Paths

Shortest Path in directed graph

- **Instance:** digraph G with n nodes, distance matrix $c: V \times V \to \mathbb{R}_0^+$ and two nodes $s, t \in V$.
- **Goal:** find the shortest path from *s* to *t* or decide that *t* is unreachable from *s*.

LP formulation using a physical analogy:

- node = ball
- edge = string (we consider a symmetric distance matrix c)
- node s is fixed, other nodes are pulled by gravity
- tightened string = shortest path Is it a polynomial problem?

```
\begin{aligned} &\max & & I_t \\ &\text{subject to:} & & \\ & & I_s = 0 \\ & & I_j \leq I_i + c_{i,j} \quad i \in 1...n, j \in 1..n \\ &\text{parameters:} & & n \in \mathbb{Z}_0^+, \ c_{i \in 1...n, j \in 1...n} \in \mathbb{R}_0^+ \\ &\text{variables:} & & I_{i \in 1...n} \in \mathbb{R}_0^+ \end{aligned}
```

Example ILP3: Traveling Salesman Problem

Asymmetric Traveling Salesman Problem

- **Instance:** complete digraph K_n $(n \ge 3)$, distance matrix $c: V \times V \to \mathbb{Q}^+$.
- Goal: find the shortest cycle (i.e. a closed oriented walk) going through all nodes.

 $x_{i,j} = 1$ iff node i is in the cycle just before node j. The enter and leave constraints do not capture the TSP completely, since any disjoint cycle (i.e. consisting of several sub-tours) will satisfy them. We use s_i , the "time" of entering node i, to **eliminate the sub-tours**.

$$\begin{array}{ll} \min & \sum_{i \in 1..n} \sum_{j \in 1..n} c_{i,j} * x_{i,j} \\ \text{subject to:} & \sum_{i \in 1..n} x_{i,j} = 1 \quad j \in 1..n \\ & \sum_{j \in 1..n} x_{i,j} = 1 \quad i \in 1..n \\ & \sum_{j \in 1..n} x_{i,j} = 1 \quad i \in 1..n \\ & \text{leave once} \\ & s_i + c_{i,j} - \left(1 - x_{i,j}\right) * M \leq s_j \quad i \in 1..n, j \in 2..n \\ & \text{parameters:} & M \in \mathbb{Z}_0^+, \ n \in \mathbb{Z}_0^+, \ c_{i \in 1..n, j \in 1..n} \in \mathbb{Q}^+ \\ & \text{variables:} & x_{i \in 1..n, j \in 1..n} \in \{0, 1\}, \ s_{i \in 1..n} \in \mathbb{R}_0^+ \end{array}$$

Algorithms

The most successful methods to solve the ILP problem are:

- Enumerative Methods
- Branch and Bounds
- Cutting Planes Methods

Ralph Gomory and Vašek Chvátal are prominent personalities in the field of ILP. Some of the solution methods are called: Gomory's Cuts or Chvátal-Gomory's cuts.

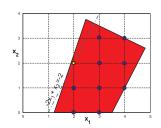

Enumerative Methods

- Based on the idea of inspecting all possible solutions.
- Due to the integer nature of the variables, the number of solutions is countable, but their number is huge. So this method is usually suited only for smaller instances with a small number of variables.
- The LP problem is solved for every combination of discrete variables.

Enumerative Methods

$$\begin{array}{llll} \max & -2x_1 & + & x_2 \\ s.t. & 9x_1 & -3x_2 \geq 11 \\ & x_1 & +2x_2 \leq 10 \\ & 2x_1 & - & x_2 \leq 7 \\ & x_1, x_2 \geq 0, & x_1, x_2 \in \mathbb{Z}_0^+ \end{array}$$

The figure below shows 10 feasible solutions. The optimal solution is $x_1 = 2, x_2 = 2$ with an objective function value of -2.

Branch and Bound Method

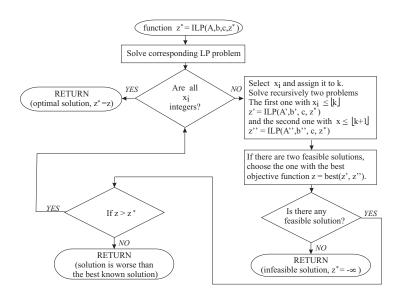

- The method is based on **splitting** the solution space into disjoint sets.
- It starts by relaxing on the integrality of the variables and solves the LP problem.
- If all variables x_i are **integers**, the computation ends. Otherwise one variable $x_i \notin \mathbb{Z}$ is chosen and its value is assigned to k.
- Then the solution space is **divided into two sets** in the first one we consider $x_i \leq \lfloor k \rfloor$ and in the second one $x_i \geq \lfloor k \rfloor + 1$.
- The algorithm recursively repeats computation for the both new sets till feasible integer solution is found.

Branch and Bound Method

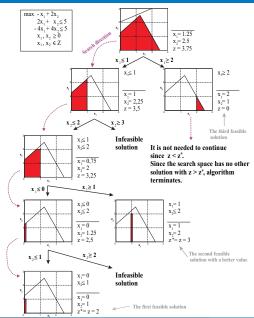

- By branching the algorithm creates a solution space which can be depicted as a tree.
- A node represents the partial solution.
- A leaf determines some (integer) solution or "bounded" branch (infeasible solution or the solution which does not give a better value than the best solution found up to now)
- As soon as the algorithm finds an integer solution, its objective function value can be used for bounding
 - The **node** is **discarded** whenever z, its (integer or real) objective function value, is worse than z*, the value of the best known solution

The ILP algorithm often uses an LP **simplex method** because after adding a new constraint it is not needed to start the algorithm again, but it allows one to continue the previous LP computation while solving the dual simplex method.

Branch and Bound

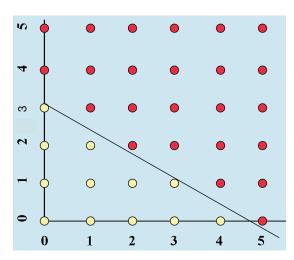

Branch and Bound - Example

ILP Solution Space

$$\max z = 3x_1 + 4x_2$$
 s.t. $5x_1 + 8x_2 \le 24$ $x_1, x_2 \in \mathbb{Z}_0^+$

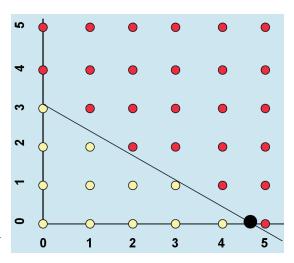

- What is optimal solution?
- Can we use LP to solve ILP problem?

Rounding is not always good choice

$$\max z = 3x_1 + 4x_2$$

- LP solution z = 14.4 for $x_1 = 4.8, x_2 = 0$
- Round, get infeasible solution $x_1 = 5, x_2 = 0$
- Truncate, get z = 12 for $x_1 = 4, x_2 = 0$
- Optimal solution is z = 13 for $x_1 = 3, x_2 = 1$

Why integer programming?

Advantages of using integer variables

- more realistic (it does not make sense to produce 4.3 cars)
- flexible e.g. binary variable can be used to model the decision (logical expression)
- we can formulate NP-hard problems

Drawbacks

- harder to create a model
- usually suited to solve the problems with less than 1000 integer variables

Special Cases of ILP - Example ILP2b: Shortest Paths

Shortest path in a graph

- Instance: digraph G, incidence matrix $w: V \times E \to \{-1,0,1\}$, distance vector $c \in \mathbb{R}_0^+$ and two nodes $s,t \in V$.
- **Goal:** find the shortest path from *s* to *t* or decide that *t* is unreachable from *s*.

LP formulation:

- $x_j = 1$ iff edge j is chosen
- For every node except s and t we enter the node as many times as we leave it

```
\begin{array}{ll} \min & \sum_{j \in 1...m} c_j * x_j \\ \text{subject to:} & \sum_{j \in 1...m} w_{s,j} * x_j & = 1 \quad \text{source } s \\ & \sum_{j \in 1...m} w_{t,j} * x_j & = -1 \quad \text{sink } t \\ & \sum_{j \in 1...m} w_{i,j} * x_j & = 0 \quad i \in V \setminus \{s,t\} \\ \text{pars:} & w_{i \in 1...n, j \in 1...m} \in \{-1,0,1\}, \ c_{j \in 1...m} \in \mathbb{R}_0^+ \\ \text{vars:} & x_{j \in 1...m} \in \mathbb{R}_0^+ \end{array}
```

The returned values of x_i are integers (binary) even though it is LP. Why?

Special Cases of ILP

The General ILP task can not be solved in polynomial time, however there are special cases which can be.

Definition - Totally unimodular matrix

Matrix $\mathbf{A} = [a_{ii}]$ of size m/n is totally unimodular if

The determinant of every square submatrix of matrix ${\bf A}$ is equal 0, +1 or -1.

Note: $a_{ij} \in \{0, 1, -1\}$ is necessary for **A** to be totally unimodular.

Totally Unimodular Matrix

Lemma

The ILP task with a totally unimodular matrix $\bf A$ and integer vector $\bf b$ can be solved by a simplex algorithm and the solution will be an integer.

Lemma

The ILP task with a totally unimodular matrix $\bf A$ and integer vector $\bf b$ can be solved in polynomial time.

Lemma

Let **A** be matrix of size m/n such that

- f 2 each column in f A contains one non-zero element or exactly two non-zero elements +1 and -1

Then matrix **A** is totally unimodular.

Problem Formulation Using ILP - Real Estate Investment

We consider 6 buildings for investment.

The price and rental income for each of them are listed in the table.

building	1	2	3	4	5	6
price[mil. Kč]	5	7	4	3	4	6
income[thousands Kč]	16	22	12	8	11	19

Goal:

maximize income

Constraints:

- investment budget is 14 mil Kč
- each building can be bought only once

Problem Formulation Using ILP - Real Estate Investment

We consider 6 buildings for investment.

The price and rental income for each of them are listed in the table.

building	1	2	3	4	5	6
price[mil. Kč]	5	7	4	3	4	6
income[thousands Kč]	16	22	12	8	11	19

Goal:

maximize income

Constraints:

- investment budget is 14 mil Kč
- each building can be bought only once

Formulation

• $x_i = 1$ if we buy building i

$$\begin{array}{lll} \max & z = 16x_1 + 22x_2 + 12x_3 + \ 8x_4 + 11x_5 + 19x_6 \\ s.t. & 5x_1 + \ 7x_2 + \ 4x_3 + \ 3x_4 + \ 4x_5 + \ 6x_6 \leq 14 \\ x_{i \in 1 \cdots 6} \in \{0, 1\} \end{array}$$

Adding Logical Formula $x_1 \Rightarrow \overline{x_3}$

Another constraint:

• If building 1 is selected, then building 3 is not selected.

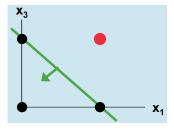

<i>x</i> ₁	<i>X</i> 3	$x_1 \Rightarrow \overline{x_3}$
0	0	1
0	1	1
1	0	1
1	1	0

Adding Logical Formula $x_1 \Rightarrow \overline{x_3}$

Another constraint:

• If building 1 is selected, then building 3 is not selected.

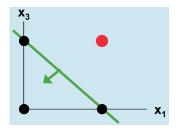

x ₁ 0 0 1	<i>x</i> ₃ 0 1 0	$\begin{vmatrix} x_1 \Rightarrow \overline{x_3} \\ 1 \\ 1 \\ 1 \\ 2 \end{vmatrix}$
1	1	0

Adding Logical Formula $x_1 \Rightarrow \overline{x_3}$

Another constraint:

• If building 1 is selected, then building 3 is not selected.

$$\begin{array}{ll} \max & z = 16x_1 + 22x_2 + 12x_3 + \ 8x_4 + 11x_5 + 19x_6 \\ s.t. & 5x_1 + \ 7x_2 + \ 4x_3 + \ 3x_4 + \ 4x_5 + \ 6x_6 \leq 14 \\ & x_1 + \ x_3 \leq 1 \\ x_{i \in 1 \cdots 6} \in \{0, 1\} \end{array}$$

Adding Logical Formula $x_2 \Rightarrow x_1$

Another constraint:

• if building 2 is selected, then building 1 is selected too

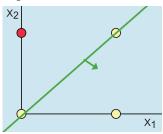

x_1	<i>x</i> ₂	$x_2 \Rightarrow x_1$
0	0	1
0	1	0
1	0	1
1	1	1

Adding Logical Formula $x_2 \Rightarrow x_1$

Another constraint:

• if building 2 is selected, then building 1 is selected too

<i>x</i> ₁ 0 0 1	x ₂ 0 1	$\begin{vmatrix} x_2 \Rightarrow x_1 \\ 1 \\ 0 \\ 1 \end{vmatrix}$
1	0	1
1	1	1

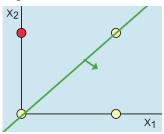

Adding Logical Formula $x_2 \Rightarrow x_1$

Another constraint:

• if building 2 is selected, then building 1 is selected too

x ₁ 0 0	<i>x</i> ₂ 0 1	$\begin{vmatrix} x_2 \Rightarrow x_1 \\ 1 \\ 0 \\ 1 \end{vmatrix}$
0	0	1
0	1	0
1	0	1
1	1	1

$$\max_{s.t.} z = 16x_1 + 22x_2 + 12x_3 + 8x_4 + 11x_5 + 19x_6$$

$$s.t. \quad 5x_1 + 7x_2 + 4x_3 + 3x_4 + 4x_5 + 6x_6 \le 14$$

$$x_2 \le x_1$$

$$x_{i \in 1 \cdots 6} \in \{0, 1\}$$

Adding Logical Formula x_2 XOR x_1

Another constraint:

• either building 4 is chosen or building 5 is chosen, but not both

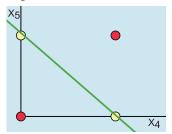

<i>x</i> ₄ 0	<i>X</i> ₅	x ₄ XOR x ₅
0	0	0
0	1	1
1	0	1
1	1	0

Adding Logical Formula x₂ XOR x₁

Another constraint:

• either building 4 is chosen or building 5 is chosen, but not both

<i>X</i> ₄	<i>X</i> 5	$\begin{array}{c c} x_4 & XOR & x_5 \\ 0 & \end{array}$
<i>x</i> ₄ 0	0	0
0	1	1
1	0	1
1	1	0

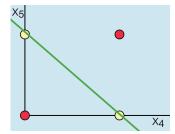

Adding Logical Formula x_2 XOR x_1

Another constraint:

• either building 4 is chosen or building 5 is chosen, but not both

x ₄ 0 0 1	<i>x</i> ₅ 0 1 0	x ₄ XOR x ₅ 0 1 1
1	0	1
1	1	0

$$\max z = 16x_1 + 22x_2 + 12x_3 + 8x_4 + 11x_5 + 19x_6$$
s.t.
$$5x_1 + 7x_2 + 4x_3 + 3x_4 + 4x_5 + 6x_6 \le 14$$

$$x_4 + x_5 = 1$$

$$x_{i \in 1 \dots 6} \in \{0, 1\}$$

Adding Logical Formula - Homework

Formulate:

- building 1 must be chosen but building 2 can not
- at least 3 estates must be chosen
- exactly 3 estates must be chosen
- if estates 1 and 2 have been chosen, then estate 3 must be chosen too $(x_1 \text{ AND } x_2) \Rightarrow x_3$
- exactly 2 estates can not be chosen

Problem Formulation Using ILP - Cloth Production

Labor costs, material demand and profit are listed in the table

product	T-shirt	shirt	trousers	capacity
labor costs	3	2	6	150
material	4	3	4	160
profit	6	4	7	

Goal:

maximize the profit

Constraints:

- labor capacity is 150 person-hours
- material capacity is 160 meters

Problem Formulation Using ILP - Cloth Production

Labor costs, material demand and profit are listed in the table

product	T-shirt	shirt	trousers	capacity
labor costs	3	2	6	150
material	4	3	4	160
profit	6	4	7	

Goal:

maximize the profit

Constraints:

- labor capacity is 150 person-hours
- material capacity is 160 meters

Formulation

• x_i is the amount of product i

$$\begin{array}{ll} \max & z = 6x_1 + 4x_2 + 7x_3 \\ s.t. & 3x_1 + 2x_2 + 6x_3 \leq 150 \\ & 4x_1 + 3x_2 + 4x_3 \leq 160 \\ x_{i \in 1 \cdots 3} & \in \mathcal{Z}_0^+ \end{array}$$

Another constraint:

• the fixed cost has to be covered to rent the machine

product	T-shirt	shirt	trousers
machine cost	200	150	100

Another constraint:

• the fixed cost has to be covered to rent the machine

product	T-shirt	shirt	trousers
machine cost	200	150	100

Formulation

- add binary variable y_i such that $y_i = 1$ when the machine producing product i is the rent
- the objective function will be changed to $\max z = 6x_1 + 4x_2 + 7x_3 200y_1 150y_2 100y_3$
- join binary y_i with integer x_i

Machine i is rented when product i is produced. We join binary y_i with integer x_i such that:

- $y_i = 0$ iff $x_i = 0$
- $y_i = 1$ iff $x_i \ge 1$

Machine i is rented when product i is produced. We join binary y_i with integer x_i such that:

- $y_i = 0$ iff $x_i = 0$
- $y_i = 1$ iff $x_i \ge 1$

For range $x_i \in \langle 0, 100 \rangle$ these relations can be written as inequalities

- $x_i \leq 100 * y_i$
- $x_i \ge y_i$...we can omit this inequality due to the objective function $(x_i = 0, y_i = 1 \text{ will not be chosen because we want } x_i \text{ to be maximal and } y_i \text{ minimal})$

Considering Several Values

Another constraint:

 Total amount of work can be 40, 80 or 120 hours in order to better fit the work contract

We only want some values of person-hours to be available:

$$3x_1 + 2x_2 + 6x_3 =$$
 either 40 or 80 or 120

Can be formulated using a set of additional variables $v_{i \in 1...3} \in \{0,1\}$ as follows:

$$3x_1 + 2x_2 + 6x_3 = 40v_1 + 80v_2 + 120v_3$$
$$\sum_{i=1}^{3} v_i = 1$$

At least One of Two Constraints Must be Valid

While modeling problems using ILP, we often need to express that the first, the second or both constraints hold. For example, $x_{i \in 1...4} \in \langle 0, 5 \rangle$, $x_{i \in 1...4} \in \mathcal{R}$

holds
$$2x_1 + x_2 \le 5$$

or $2x_3 - x_4 \le 2$
or both

This can be modeled by a big M, i.e. big positive number (here 15), and variable $y \in \{0,1\}$ so it can "switch off" one of the inequalities.

$$2x_1 + x_2 \le 5 + M \cdot y 2x_3 - x_4 \le 2 + M \cdot (1 - y)$$

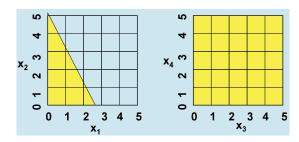

At least One of Two Constraints Must be Valid

for y = 0 inequalities:

$$2x_1 + x_2 \le 5 + M \cdot y 2x_3 - x_4 \le 2 + M \cdot (1 - y)$$

reduce to:

$$2x_1+x_2\leq 5$$

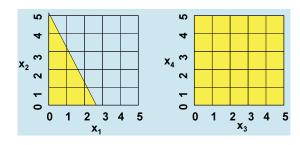

At least One of Two Constraints Must be Valid

for y = 0 inequalities:

$$2x_1 + x_2 \le 5 + M \cdot y 2x_3 - x_4 \le 2 + M \cdot (1 - y)$$

reduce to:

$$2x_1+x_2\leq 5$$

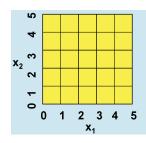

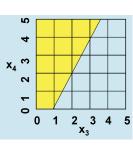

for y = 1 inequalities:

$$2x_1 + x_2 \le 5 + M \cdot y 2x_3 - x_4 \le 2 + M \cdot (1 - y)$$

reduce to:

$$2x_3 - x_4 < 2$$

At least One of Two Constraints Must be Valid - Homework

• Find the solution space of the system of inequalities:

$$2x_1 + x_2 \le 5 + M \cdot y 2x_1 - x_2 \le 2 + M \cdot (1 - y) y \in \{0, 1\}$$

• Find the solution space of the system of inequalities. Note that the equations correspond to parallel lines. Is it possible to find x_1, x_2 such that both equations are valid simultaneously?

$$2x_1 + x_2 \le 5 + M \cdot y$$

$$2x_1 + x_2 \ge 10 + M \cdot (1 - y)$$

$$y \in \{0, 1\}$$

At least One of Two Constraints Must be Valid Example: Non-preemptive Scheduling

$1\left|r_{j},\widetilde{d}_{j}\right|$ C_{max} ... NP-hard problem

- **Instance:** A set of non-preemptive tasks $\mathcal{T} = \{T_1, \dots, T_i, \dots T_n\}$ with release date r and deadline \widetilde{d} should be executed on one processor. The processing times are given by vector p.
- **Goal:** Find a feasible schedule represented by start times s that minimizes completion time $C_{max} = \max_{i \in \langle 1, n \rangle} s_i + p_i$ or decide that it does not exist.
 - processor joiner
 - \bullet T_i chair to be produced
- Example: r_i time, when the material is available
 - \bullet \widetilde{d}_i time when the chair must be completed
 - \circ s_i time when the chair production starts

At least One of Two Constraints Must be Valid Example: Non-preemptive Scheduling

Since at the given moment, at most, one task is running on a given resource, therefore, for all task pairs T_i , T_j it must hold:

- T_i precedes T_i $(s_i \ge s_i + p_i)$
- ② or T_j precedes T_i $(s_i \ge s_j + p_j)$

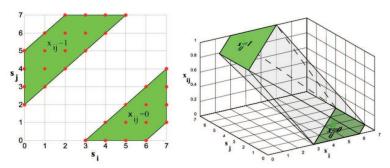

Note that (for $p_i > 0$) both inequalities can't hold simultaneously. We need to formulate that at least one inequality holds. We will use variable $x_{ij} \in \{0,1\}$ such that $x_{ij} = 1$ if T_i preceds T_j . For every pair T_i , T_j we introduce inequalities:

$$s_j + M \cdot (1 - x_{ij}) \ge s_i + p_i$$

 $s_i + M \cdot x_{ij} \ge s_i + p_i$

"switched off" when $x_{ij} = 0$ "switched off" when $x_{ij} = 1$

Scheduling - Illustration of Non-convex Space

Non-convex 2D space is a projection of two cuts of a 3D polytope (determined by the set of inequalities) in planes x = 0 and x = 1.

At least K of N Constraints Must Hold

We have N constraints and we need at least K of them to hold. Constraints are of type:

$$f(x_1, x_2, \dots, x_n) \leq b_1$$

$$f(x_1, x_2, \dots, x_n) \leq b_2$$

$$\vdots$$

$$f(x_1, x_2, \dots, x_n) \leq b_N$$

Can be solved by introducing N variables $y_{i \in 1...N} \in \{0,1\}$ such that

$$f(x_1, x_2, ..., x_n) \le b_1 + M \cdot y_1$$

 $f(x_1, x_2, ..., x_n) \le b_2 + M \cdot y_2$
 \vdots
 $f(x_1, x_2, ..., x_n) \le b_N + M \cdot y_N$
 $\sum_{i=1}^{N} y_i = N - K$

If K = 1 and N = 2 we can use just one variable y_i and represent its negation as a $(1 - y_i)$, see above slides for details.

ILP Solvers

- CPLEX proprietary http://www.ilog.com/products/cplex/
- MOSEK proprietary http://www.mosek.com/
- GLPK free http://www.gnu.org/software/glpk/
- LP_SOLVE free http://groups.yahoo.com/group/lp_solve/
- GUROBI

YALMIP - Matlab toolbox for modelling ILP problems

Cutting Planes Method

Another group of algorithms are cutting planes methods. Its general idea is (similarly to the branch and bound method) to repeat the solution of LP problems. It iteratively adds a constraint that cuts off part of the solution space. The new constraint must fulfill these conditions:

- The solution found by LP becomes infeasible
- All integer solutions feasible in the last step have to remain feasible.

Among the best known methods are Dantzig Cuts, Gomory Cuts and Chvátal-Gomory Cuts.

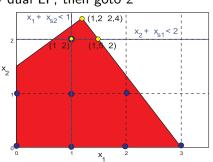

Gomory Cuts

Algorithm

- (Initialization) Solve the problem as an LP by a simplex algorithm
- Optimality test) If the solution is an integer, the computation ends
- (Reduction) Add new constraint (Gomory cut) into the simplex table. Optimize the problem by dual LP, then goto 2

min
$$x_1 + 2x_2$$

 $s.t. -3x_1 + 4x_2 \le 6$
 $4x_1 + 3x_2 \le 12$
 $x_1, x_2 \ge 0, x_1, x_2 \in Z$

ILP - Conclusion

- NP-complete problem.
- Used to formulate majority of combinatorial problems.
- Often solved by branch and bound method.
