Based on [Berg] and [Mount]

Version from 13.11.2014

Talk overview

- **Polygon** triangulation

- Monotone polygon triangulation
- Monotonization of non-monotone polygon

- **Delaunay triangulation (DT)** of **points**

- Input: set of 2D points
- Properties
- Incremental Algorithm
- Relation of DT in 2D and lower envelope (CH) in 3D and
relation of VD in 2D to upper envelope in 3D

Polygon triangulation problem

- Triangulation (in general)
= subdividing a spatial domain into simplices
- Application
 - decomposition of complex shapes into simpler shapes
 - art gallery problem (how many cameras and where)
- We will discuss
 - a simple polygon triangulation
 - without demand on triangle shapes
- Complexity of polygon triangulation
 - $O(n)$ alg. exists [Chazelle91], but it is too complicated
 - practical algorithms run in $O(n \log n)$

Terminology

Simple polygon

= region enclosed by a closed polygonal chain that does not intersect itself

Visible points

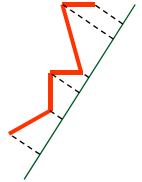

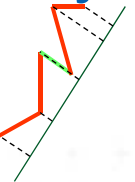

= two points on the boundary are visible if the interior of the line segment joining them lies entirely in the interior of the polygon

Diagonal

= line segment joining any pair of visible vertices

Terminology

- A polygonal chain C is **strictly monotone with respect to line L** , if any line orthogonal to L intersects C in at most one *point* 
- A chain C is **monotone with respect to line L** , if any line orthogonal to L intersects C in at most one *connected component* (point, line segment,...) 
- Polygon P is **monotone with respect to line L** , if its boundary ($\text{bnd}(P)$, ∂P) can be split into two chains, each of which is monotone with respect to L

Terminology

- **Horizontally monotone polygon**
= monotone with respect to x -axis
 - Can be tested in $O(n)$
 - Find leftmost and rightmost point in $O(n)$
 - Split boundary to **upper and lower chain**
 - Walk left to right, verifying that x -coord are non-decreasing

x-monotone polygon

[Mount]

Terminology

- Every simple polygon can be triangulated
- Simple polygon with n vertices consists of
 - exactly $n-2$ triangles
 - exactly $n-3$ diagonals
 - Each diagonal is added once
=> $O(n)$ sweep line algorithm exist

Proof by induction

$n = 3 \Rightarrow 0$ diagonal

$n = 4 \Rightarrow 1$ diagonal

$n := n+1 \Rightarrow n+1-3$ diagonals
 $n+1 = 7 \Rightarrow 4$ diagonals)

Simple polygon triangulation

- Simple polygon can be triangulated in 2 steps:
 1. Partition the polygon into x-monotone pieces
 2. Triangulate all monotone pieces

(we will discuss the steps in the reversed order)

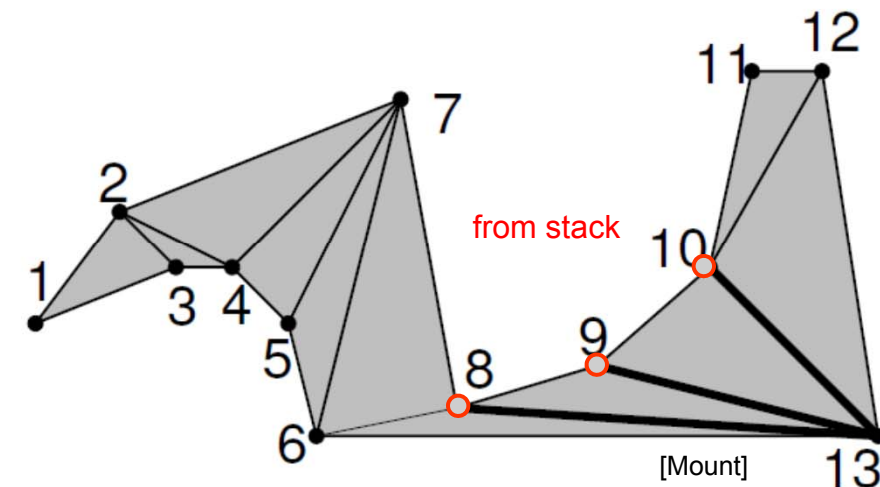

2. Triangulation of the monotone polygon

- Sweep left to right
- Triangulate everything you can by adding diagonals between visible points
- Remove triangulated region from further consideration – mark as DONE

Triangulation of the monotone polygon

Main invariant of the untriangulated region

Main invariant

- Let v_i be the vertex being just processed
- The **untriangulated region** left of v_i consists of **two x-monotone chains** (upper and lower)
- Each chain has at least one edge
- If it has more than one edge
 - these edges form a **reflex chain**
 - = sequence of vertices with interior angle $\geq 180^\circ$

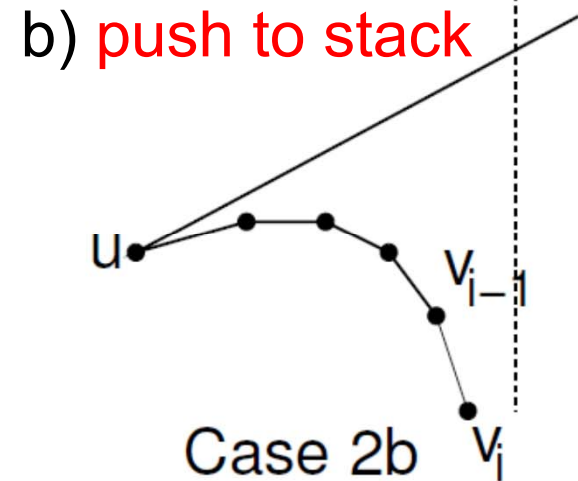

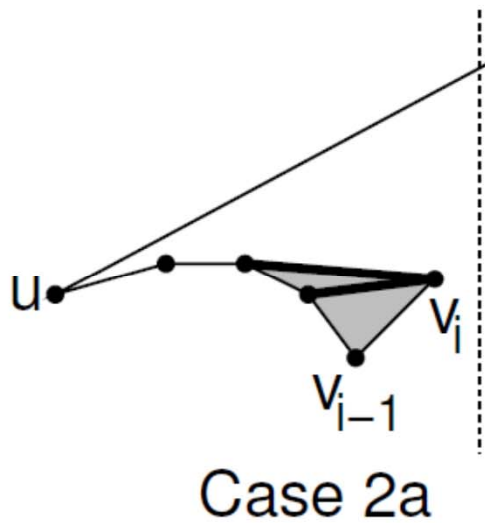

- Left vertex of the last added diagonal is u
- Vertices between u and v_i are waiting in the **stack**

Triangulation cases

- Case 1: v_i lies on the **opposite chain**
 - **Add diagonals** from $\text{next}(u)$ to v_{i-1}
 - Set $u = v_{i-1}$. Last diagonal (invariant) is $v_i v_{i-1}$
- Case 2: v is on the **same chain** as v_{i-1}
 - a) **walk back**, adding diagonals joining v_i to prior vertices until the angle becomes $> 180^\circ$ or u is reached - **pop**)

[Mount]

1. Polygon subdivision into monotone pieces

- X-monotonicity breaks the polygon in vertices with edges directed **both left** or **both right**

- The monotone polygons parts are separated by the **splitting diagonals** (joining **vertex and helper**)

Splitting diagonals

Monotone decomposition

[Mount]

Data structures for subdivision

■ Events

- Endpoints of edges, known from the beginning
- Can be stored in sorted list – no priority queue

■ Sweep status

- List of edges intersecting sweep line (top to bottom)
- Stored in $O(\log n)$ time dictionary (like balanced tree)

■ Event processing

- Six event types based on local structure of edges around vertex v

Helper – definition

helper(e_a)

= the rightmost vertically visible processed vertex u
below edge e_a on polygonal chain between edges e_a & e_b

is visible to every point along the sweep line between e_a & e_b

○ = vertically visible
processed vertex

all these vertices
see $u = \text{helper}(e_a)$ ○

v = current vertex
(sweep line stop)

Helper

$\text{helper}(e_a)$

is defined only for edges intersected by the sweep line

Six event types of vertex v

1. Split vertex

- Find edge e above v ,
connect e with $\text{helper}(e)$ by diagonal
- Add 2 new edges incident to v into SL status
- Set new **$\text{helper}(e) = \text{helper}(\text{lower edge of these two}) = v$**

2. Merge vertex

- Find two edges incident with v in SL status
- Delete both from SL status
- Let e is edge immediately above v
- Make **$\text{helper}(e) = v$**

[Mount]

(Interior angle $> 180^\circ$ for both – split & merge vertices)

Six event types of vertex v

3. Start vertex

- Both incident edges lie right from v
- But interior angle $< 180^\circ$
- Insert both edges to SL status
- Set **helper(upper edge)** = v

4. End vertex

- Both incident edges lie left from v
- But interior angle $< 180^\circ$
- Delete both edges from SL status
- No helper set – we are out of the polygon

[Mount]

Six event types of vertex v

5. Upper chain-vertex

- one side is to the left, one side to the right, interior is below
- replace the left edge with the right edge in SL status
- Make v **helper** of the new (upper) edge

6. Lower chain-vertex

- one side is to the left, one side to the right, interior is above
- replace the left edge with the right edge in SL status
- Make v **helper** of the edge e above

[Mount]

Polygon subdivision complexity

- Simple polygon with n vertices can be partitioned into x-monotone polygons in
 - $O(n \log n)$ time (n steps of SL, log n search each)
 - $O(n)$ storage

Dual graph G for a Voronoi diagram

Graph G : **Node** for each Voronoi-diagram cell $V(p) \sim$ VD site p

Arc connects neighboring cells
(arc for every voronoi edge)

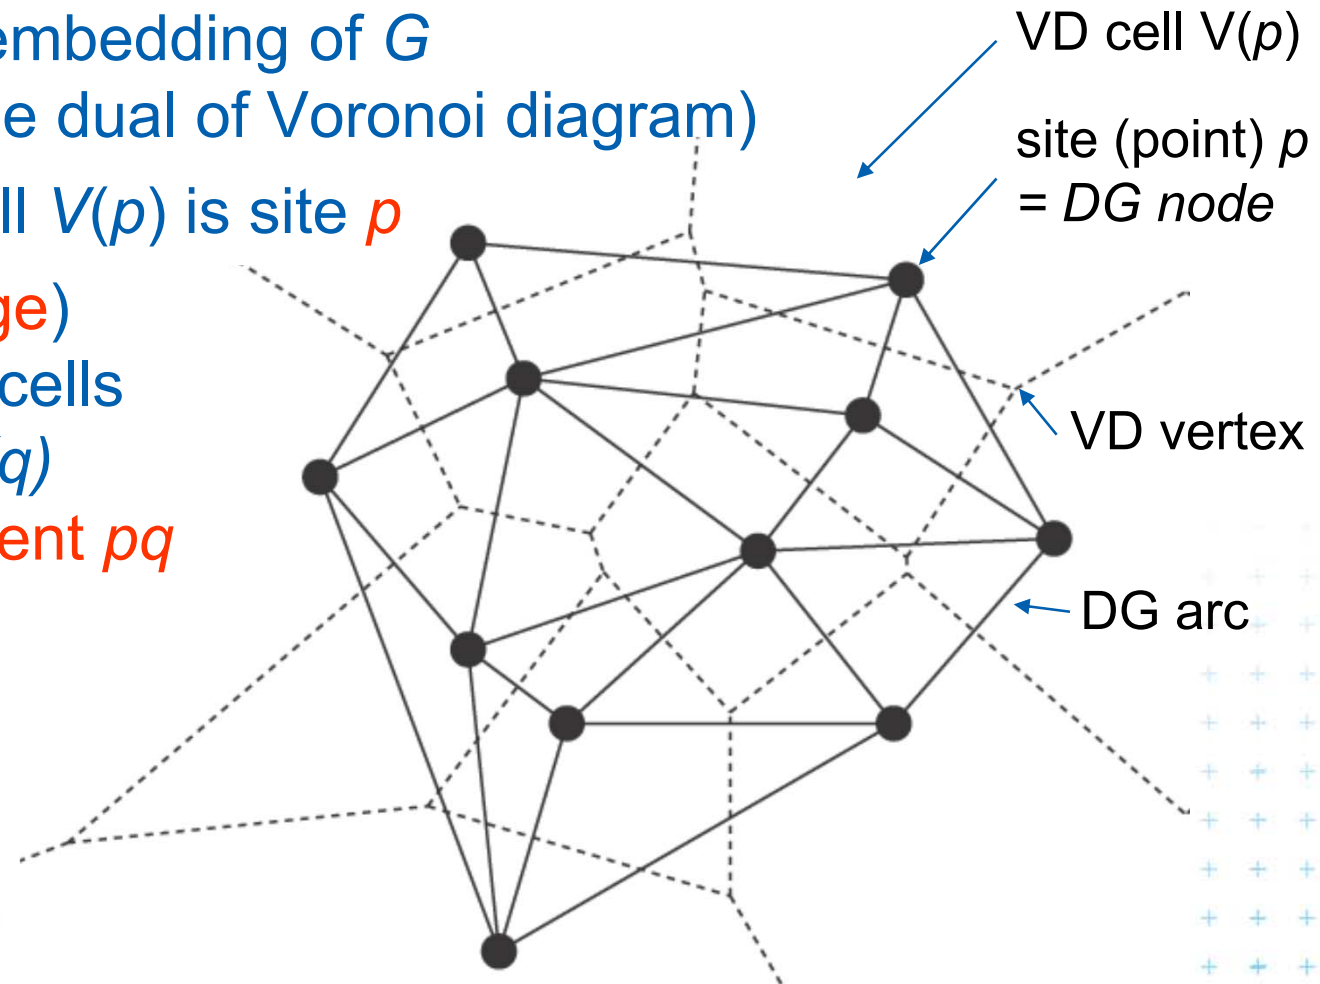

Delaunay graph $DG(P)$

[Борис Николаевич Делоне]

= straight line embedding of G
(straight-line dual of Voronoi diagram)

- **Node** for cell $V(p)$ is site p
- **Arc (DT edge)** connecting cells $V(p)$ and $V(q)$ is the **segment pq**

Delaunay graph and Delaunay triangulation

- *Delaunay graph* $DG(P)$ has convex polygonal faces (with number of vertices ≥ 3 , equal to the degree of Voronoi vertex)

- *Delaunay triangulation* $DT(P)$ = Delaunay graph for sites in general position

- No four sites on a circle
- Faces are **triangles** (Voronoi vertices have **degree = 3**)
- DT is unique (DG not! Can be triangulated differently)

[Berg]

$DG(P)$ sites not in general position

- Triangulate larger faces – such triangulation is not unique

Circumcircle property

- The **circumcircle** of any triangle in DT is **empty** (no sites)
Proof: It's center is the Voronoi vertex
- Three points a, b, c are **vertices of the same face** of $DG(P)$ **iff** circle through a, b, c contains no point of P in its interior

Empty circle property and legal edge

- Two points a, b form an **edge of $DG(P)$** – it is a **legal edge** **iff** \exists closed disc with a, b on its boundary that contains no other point of P in its interior
- ... disc minimal diameter = $\text{dist}(a, b)$

Closest pair property

- The closest pair of points in P are neighbors in $DT(P)$

Delaunay triangulation properties

2/2

- DT edges do not intersect
- Triangulation T is **legal**, iff T is a Delaunay triangulation (i.e., if it does not contain illegal edges)
- Edge that was legal before **may become illegal** if one of the triangles incident to it changes
- In convex quadrilateral $abcd$ ($abcd$ do not lie on common circle) **exactly one** of ac , bd is an illegal edge = principle of **edge flip** operation

Edge flip operation

Edge flip

= a local operation, that increases the angle vector

- Given two adjacent triangles $\triangle abc$ and $\triangle cda$ such that their union forms a convex quadrilateral, the **edge flip** operation **replaces the diagonal ac with bd** .

[Berg]

Delaunay triangulation

- Let T be a triangulation with m triangles (and $3m$ angles)
- **Angle-vector**
= non-decreasing ordered sequence $(\alpha_1, \alpha_2, \dots, \alpha_{3m})$
inner angles of triangles, $\alpha_i \leq \alpha_j$, for $i < j$
- Delaunay triangulation has the **lexicographically largest angle sequence**
 - It maximizes the minimal angle (the first angle in angle-vector)
 - It maximizes the second minimal angle, ...
 - It maximizes all angles
 - It is an **angle optimal triangulation**

Thales's theorem (624-546 BC)

Respective Central Angle Theorem

- Let $C =$ circle,
- $l =$ line intersecting C in points a, b
- $p, q, r, s =$ points on the same side of l
 p, q on C , r is in, s is out
- Then for the angles holds:
 $\sphericalangle arb > \sphericalangle apb = \sphericalangle aqb > \sphericalangle asb$

<http://www.mathopenref.com/arccentralangletheorem.html>

Edge flip of illegal edge and angle vector

- The **minimum angle increases** after the edge flip

$bd < ac$ $\varphi_{ab} > \theta_{ab}$ $\varphi_{bc} > \theta_{bc}$ $\varphi_{cd} > \theta_{cd}$ $\varphi_{da} > \theta_{da}$ [Mount]

=> After limited number of edge flips

- Terminate with lexicographically maximum triangulation

It satisfies the empty circle condition => Delauney T

Incremental algorithm principle

1. Create a large triangle containing all points
(to avoid problems with unbounded cells)
 - must be larger than the largest circle through 3 points
 - will be discarded at the end
2. Insert the points in random order
 - Find triangle with inserted point p
 - Add edges to its vertices
(these new edges are correct)
 - Check correctness of the old edges (triangles)
“around p ” and legalize (flip) potentially illegal edges
3. Discard the large triangle and incident edges

Incremental algorithm in detail

DelaunayTriangulation(P)

Input: Set P of n points in the plane

Output: A Delaunay triangulation T of P

1. Let p_{-2}, p_{-1}, p_0 form a triangle large enough to contain P
2. Initialize T as the triangulation consisting a single triangle $p_{-2}p_{-1}p_0$
3. Compute **random permutation** p_1, p_2, \dots, p_n of $P \setminus \{p_0\}$
4. **for** $r = 1$ **to** n **do**
5. $T = \text{Insert}(p_r, T)$
6. Discard p_{-1}, p_{-2}, p_{-3} with all incident edges from T
7. **return** T

Incremental algorithm – insertion of a point

Insert(p, T)

Input: Point p being inserted into triangulation T

Output: Correct Delaunay triangulation after insertion of p

1. Find a triangle $abc \in T$ containing p
2. **if** p lies **in the interior** of abc **then**
3. Insert edges pa, pb, pc into triangulation T
 (splitting abc into 3 triangles pab, pbc, pca)
4. LegalizeEdge(p, ab, T)
5. LegalizeEdge(p, bc, T)
6. LegalizeEdge(p, ca, T)
7. **else** // p lies **on the edge** of abc , say ab , point d is right from edge ab
8. Remove ab and insert edges pa, pb, pc, pd into triangulation T
 (splitting abc and abd into 4 triangles pad, pdb, pbc, pca)
9. LegalizeEdge(p, ab, T)
10. LegalizeEdge(p, bc, T)
11. LegalizeEdge(p, cd, T)
12. LegalizeEdge(p, da, T)
13. **return** T

Incremental algorithm – edge legalization

LegalizeEdge(p, ab, T)

Input: Edge ab being checked after insertion of point p to triangulation T

Output: Delaunay triangulation of $p \cup T$

1. if(ab is edge on the exterior face) return
2. let d be the vertex to the right of edge ab
3. if(inCircle(p, a, d, b)) // d is in the circle around $pab \Rightarrow d$ is illegal
4. Flip edge ab for pd
5. LegalizeEdge(p, ad, T)
6. LegalizeEdge(p, db, T)

Insertion of p may make edges ab, bc & ca illegal
(circle around pab will contain point d)

After edge flip, the edge pd will be legal
(the circumcircles of the resulting triangles pdb , and pad will be empty)

We must check and possibly flip edges ad, db

Correctness of edge flip of illegal edge

- Assume point p is in C (it violates DT criteria for adb)
- adb was a triangle of DT $\Rightarrow C$ was an empty circle
- Create circle C' through point p , C' is inscribed to C , $C' \subset C$
 $\Rightarrow C'$ is also an empty circle
 \Rightarrow new edge pd is a Delaunay edge

DT- point insert and mesh legalization

Every new edge created due to insertion of p will be incident to p

Delaunay triangulation – other point insert

insert p
check pab

- Legalize now
- Legalize later
- Legal edge

[Mount]

Delaunay triangulation – other point insert

flip(ab)
check pad

- Legalize now
- Legalize later
- Legal edge

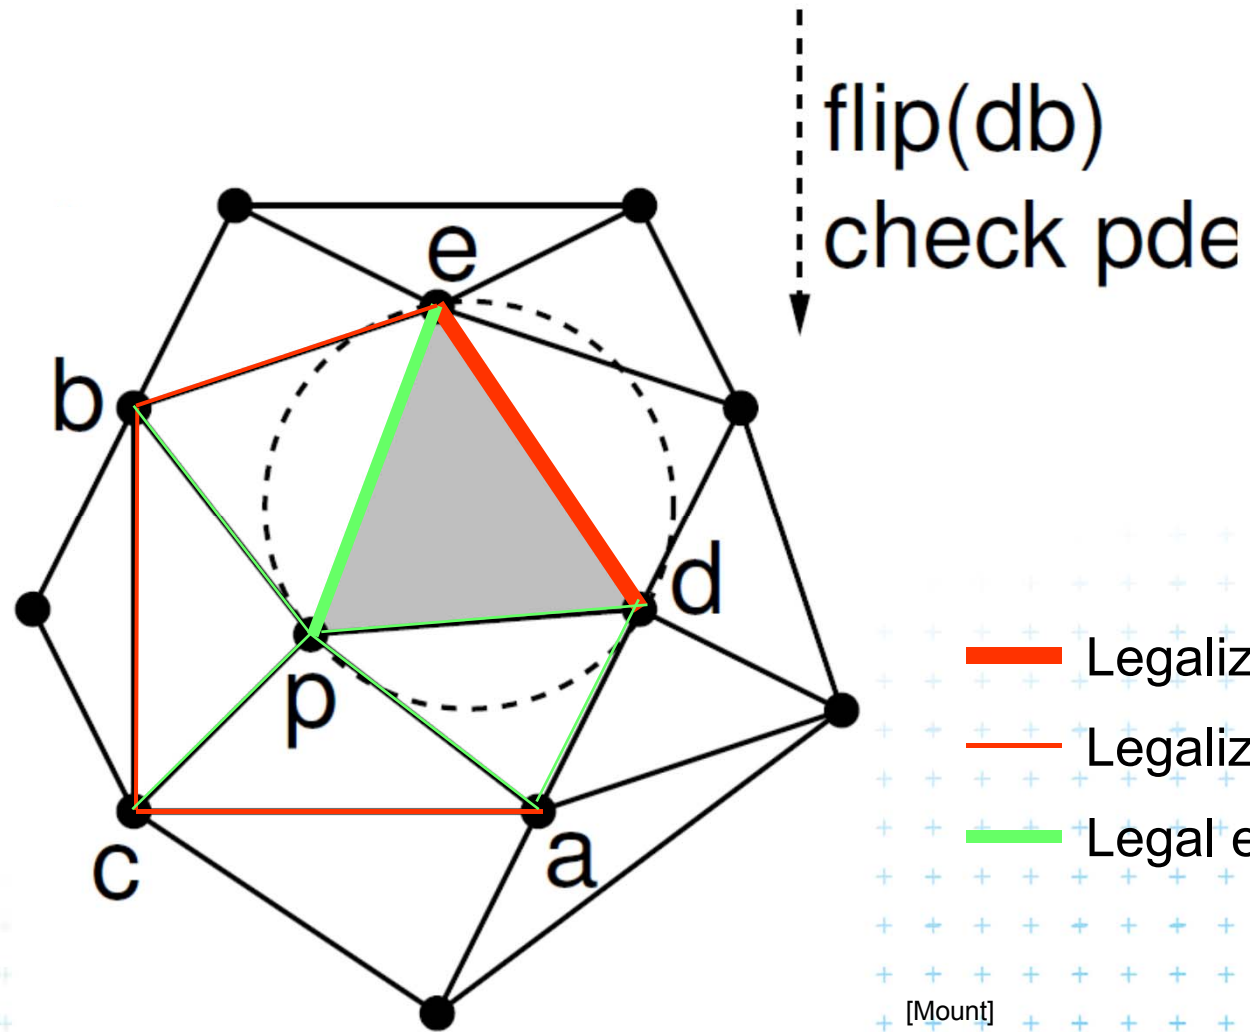

[Mount]

Delaunay triangulation – other point insert

Delaunay triangulation – other point insert

Delaunay triangulation – other point insert

Delaunay triangulation – other point insert

Delaunay triangulation – other point insert

[Mount]

Delaunay triangulation – other point insert

Delaunay triangulation – other point insert

Correctness of the algorithm

- Every **new edge** (created due to insertion of p)
 - is incident to p
 - must be legal
 - => no need to test them
- Edge can only become **illegal** if one of its incident triangle changes
 - Algorithm tests any edge that may become illegal
 - => the algorithm is correct
- Every **edge flip** makes the angle-vector larger
- => algorithm can never get into infinite loop

Point location data structure

- For finding a triangle $abc \in T$ containing p
 - Leaves for active (current) triangles
 - Internal nodes for destroyed triangles
 - Links to new triangles
- Search p : start in root (initial triangle)
 - In each inner node of T :
 - Check all children (max three)
 - Descend to child containing p

Point location data structure

Simplified
- it should contain the root node

split Δ_1

DCGI

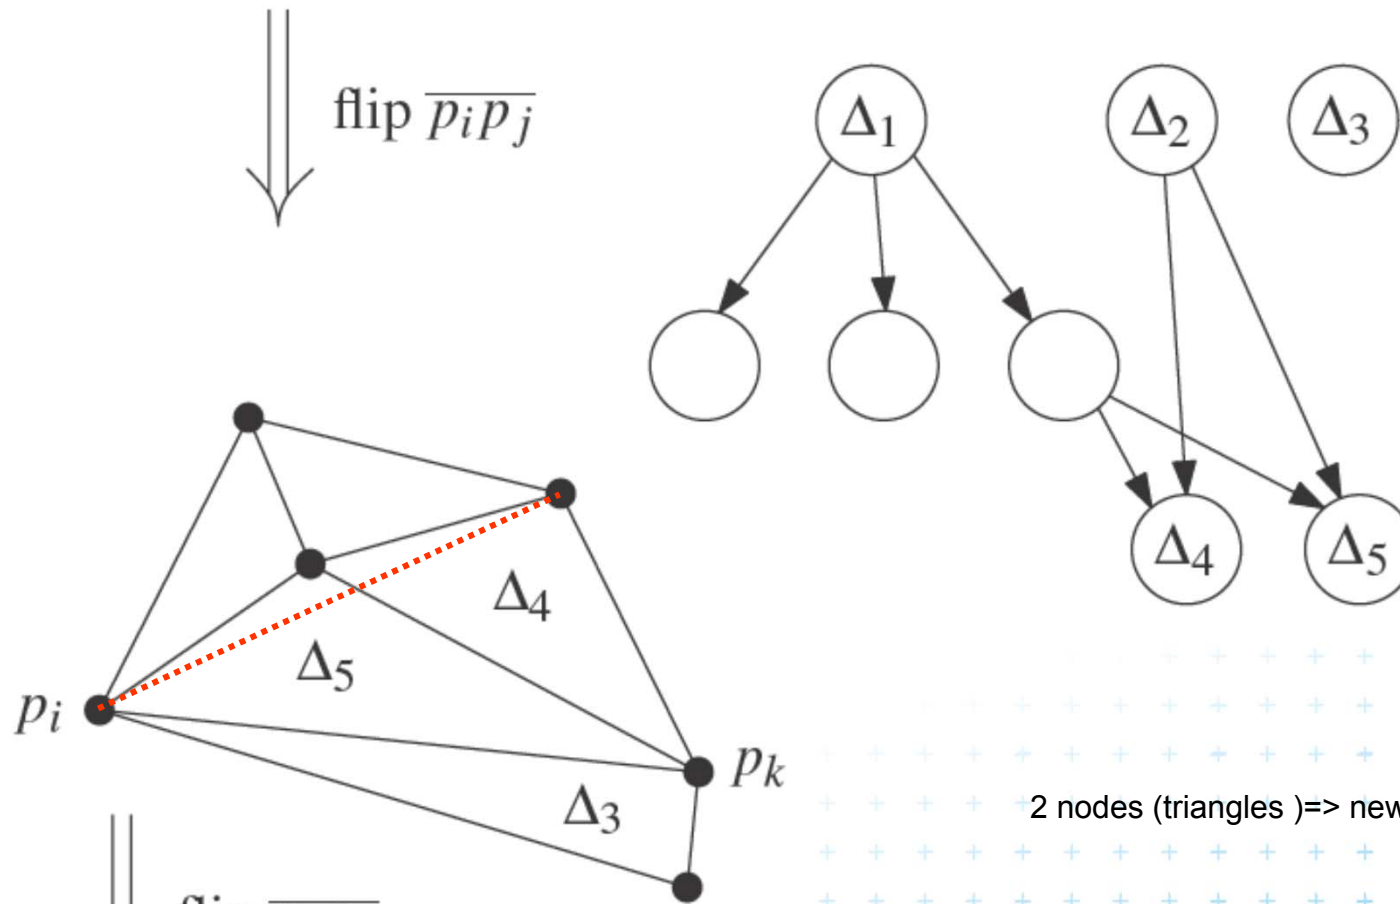

[Berg]

Point location data structure

Point location data structure

2 nodes (triangles) => new 2 nodes

[Berg]

Point location data structure

InCircle test

- a, b, c are counterclockwise in the plane
- Test, if d lies to the left of the oriented circle through a, b, c

$$\text{inCircle}(a, b, c, d) = \det \begin{pmatrix} a_x & a_y & a_x^2 + a_y^2 & 1 \\ b_x & b_y & b_x^2 + b_y^2 & 1 \\ c_x & c_y & c_x^2 + c_y^2 & 1 \\ d_x & d_y & d_x^2 + d_y^2 & 1 \end{pmatrix} > 0$$

[Mount]

Creation of the initial triangle

- For given points set P
- Initial triangle $p_{-2}p_{-1}p_0$
 - Must contain all points of P
 - Must not be (none of its points) in any circle defined by non-collinear points of P

- l_{-2} = horizontal line above P
- l_{-1} = horizontal line below P
- p_{-2} = lies on l_{-2} as far left that p_{-2} lies outside every circle
- p_{-1} = lies on l_{-1} as far right that p_{-1} lies outside every circle defined by 3 non-collinear points of P

- Symbolical tests with this triangle $\Rightarrow p_{-1}$ and p_{-2} always

Complexity of incremental DT algorithm

- Delaunay triangulation of a set P in the plane can be computed in
 - $O(n \log n)$ expected time
 - using $O(n)$ storage
- For details see [Berg, Section 9.4]

Delaunay triangulations and Convex hulls

- Delaunay triangulation in R^d can be computed as part of the convex hull in R^{d+1}
- 2D: Connection is the paraboloid: $z = x^2 + y^2$

Project onto paraboloid.

Compute convex hull.

Project hull faces back to plane..

Vertical projection of points to paraboloid

- Vertical projection of 2D point to paraboloid in 3D

$$(x, y) \rightarrow (x, y, x^2 + y^2)$$

- Lower convex hull
= portion of CH visible from $z = -\infty$

[Rourke]

Relation between CH and DT

- Delaunay condition (2D)

Points $p, q, r \in S$ form a Delaunay triangle **iff** the **circumcircle of p, q, r is empty** (contains no point)

- Convex hull condition (3D)

Points $p', q', r' \in S'$ form a face of $CH(S')$ **iff** the **plane passing through p', q', r' is supporting S'**

- all other points lie to one side of the plane
- plane passing through p', q', r' is supporting hyperplane of the convex hull $CH(S')$

Relation between CH and DT

[Rourke]

- 4 distinct points p, q, r, s in the plane, and let p', q', r', s' be their respective projections onto the paraboloid, $z = x^2 + y^2$.
- The point s lies within the circumcircle of pqr iff s' lies on the lower side of the plane passing through p', q', r' .

Tangent plane to paraboloid

- Non-vertical **tangent plane** through $(a, b, a^2 + b^2)$

- Paraboloid $z = x^2 + y^2$

- Derivation at this point

$$\frac{\partial z}{\partial x} = 2x \qquad \frac{\partial z}{\partial y} = 2y$$

- Evaluates to $2a$ and $2b$

- Plane: $z = 2ax + 2by + \gamma$

$$a^2 + b^2 = 2a \cdot a + 2b \cdot b + \gamma$$

$$\gamma = -(a^2 + b^2)$$

- **Tangent plane** through point $(a, b, a^2 + b^2)$

$$z = 2ax + 2by - (a^2 + b^2)$$

Plane intersecting the paraboloid

- Non-vertical **tangent plane** through $(a, b, a^2 + b^2)$

$$z = 2ax + 2by - (a^2 + b^2)$$

- Shift this plane r^2 upwards \rightarrow **secant plane** intersects the paraboloid in an **ellipse** in 3D

$$z = 2ax + 2by - (a^2 + b^2) + r^2$$

- Eliminate z (project to 2D) $z = x^2 + y^2$

$$x^2 + y^2 = 2ax + 2by - (a^2 + b^2) + r^2$$

- This is a **circle** projected to 2D with center (a, b) :

$$(x - a)^2 + (y - b)^2 = r^2$$

[Mount]

Tangent and secant planes

Cross section of the paraboloid

Secant plane

Tangent plane

Circle in xy plane

- Note: the circle is moved a little down
- points p and q should lie in the xy plane
- the circle too

Secant plane defined by three points

Test inCircle – meaning in 3D

- Points p, q, r are counterclockwise in the plane
- Test, if s lies **in the circumcircle** of Δpqr is equal to
 - = test, whether s' lies within a lower half space of the plane passing through p', q', r' (3D)
 - = test, if quadruple p', q', r', s' is positively oriented (3D)
 - = test, if s lies to the left of the oriented circle through abc (2D)

$$\text{in}(p, q, r, s) = \det \begin{pmatrix} p_x & p_y & p_x^2 + p_y^2 & 1 \\ q_x & q_y & q_x^2 + q_y^2 & 1 \\ r_x & r_y & r_x^2 + r_y^2 & 1 \\ s_x & s_y & s_x^2 + s_y^2 & 1 \end{pmatrix} > 0.$$

An the Voronoi diagram?

- VD and DT are dual structures
- **Points** and **lines** in the plane are dual to **points** and **planes** in 3D space
- **VD of points in the plane** can be transformed to **intersection of halfspaces in 3D space**

Voronoi diagram as upper envelope in \mathbb{R}^{d+1}

- For each point $p = (a, b)$ a tangent plane to the paraboloid is $z = 2ax + 2by - (a^2 + b^2) + r^2$
- $H^+(p)$ is the set of points above this plane

$$H^+(p) = \{(x, y, z) \mid z \geq 2ax + 2by - (a^2 + b^2) + r^2\}$$

- *VD of points in the plane can be computed as intersection of halfspaces $H^+(p_i)$*
- *This intersection of halfspaces = unbounded convex polyhedron = upper envelope of halfspaces $H^+(p_i)$*

Voronoi diagram as upper envelope in 3D

[Fukuda]

Derivation of projected Voronoi edge

- **2 points:** $p = (a, b)$ and $q = (c, d)$ in the plane

$$z = 2ax + 2by - (a^2 + b^2) \quad \text{Tangent planes}$$

$$z = 2cx + 2dy - (c^2 + d^2) \quad \text{to paraboloid}$$

- Intersect the planes, project onto xy (eliminate z)

$$x(2a - 2c) + y(2b - 2d) = (a^2 - c^2) + (b^2 - d^2)$$

- This **line** passes through midpoint between p and q

$$\frac{a+c}{2}(2a - 2c) + \frac{b+d}{2}(2b - 2d) = (a^2 - c^2) + (b^2 - d^2)$$

- It is perpendicular bisector with slope

$$-\frac{(a - c)}{(b - d)}$$
